Abstract

Transport in itself is a very fundamental need of people, after food and housing, possibly one of the strongest. Urban transport directly affects the economic efficiency of cities and the well-being of their inhabitants. Rapid urbanization and booming of motorized vehicles in developing countries have put high pressure on urban transport systems. Traffic congestion is experienced almost every day. *"Improved mobility = Improved prosperity"* But the question for many developing cities is how to relieve traffic congestion and improve mobility?

The traditional approach to urban transport was to "build away" the problems by producing more urban roads and highways to favour the movement of vehicles. This strategy seems to be logical, but the lesson drawn is that it is not effective way. Recently, urban planners have realized that infrastructure alone will not solve traffic problems; only through the integration of land-use and transport in combination with promotion of good public transport and restriction of private vehicle use sustainable transport can be achieved. From literature, there are two main directions in the integration of land-use and transport: that is mixed land-uses and relocation of some major land uses such as offices, hospitals, etc. for example out of the city centre. The purpose of integrating land-use and transport is to move local and regional spatial structures in the direction of:

- Reducing the demand for transport (including number of trip and travel time/distance),
- Increasing the choice of available transport and reducing dependence on motorized mode,
- Improving accessibility to job, public services
- Supporting the efficient and viable operation of public transport services, walking and cycling
- Enhancing healthy conditions for living.

Hanoi is the capital and biggest centre of politics, culture, education, technology and the second centre of economics in Vietnam. Like other Asian cities, traffic congestion is experienced during peak hours every morning on some corridors leading into the city centre and in the afternoon in the reverse direction.

Recently, the government has adopted a policy to expand the city to the West. As a result, many organizations want to move out from the city centre.

Against this background, the main aim of this research is to evaluate the contribution of some selected major land uses to the traffic congestion of some corridors and test some scenarios of relocating selected some major land uses to see if it can relieve traffic congestion and improve accessibility for the people of Hanoi. Five hospitals, three universities and two government offices were targeted for office-based interview to retrieve the trip origins, travel time, travel length, transport mode and routes used. The research has revealed that there is an imbalance in the distribution of some major land-uses like hospitals, universities and government offices within the Hanoi region as well as a high separation between these major land-uses and residential areas. Most of the government offices are located in the core centre (Hoan Kiem district) and Ba Dinh district with number of staff at national level are 16,218 and 93,331 respectively. With a total of almost 70,000 students, these three universities are very attractive for not only bachelor students but also for students of second-degree, in-service and higher education courses. Bachelor students already account for 50% of total students and among them student from Hanoi is account for 23.7%. In the morning, only 2% of students commute during peak

hour since they start the lesson very early but in the afternoon more than 90% of the students commute during peak hour. It also means that 89% of the students contribute to congestion on some corridors. Over 80% of government officers, hospital staffs and teaching staffs own private motorcycle and more than 80% of them commute during congestion in both morning and afternoon peak hours. That is why one can see huge number of people travelling on main corridors leading to the city centre and in the reverse direction in the afternoon with very low speed of 1.5 to 2.5 m/s (about from 5km/h to 9km/h).

It turns out that these land-uses contribute considerably to traffic congestion of some corridors nearby. For example, the study area no.1 has considerable contribution to Chua Boc, Pham Ngoc Thach, and Thai Ha streets with shares of about 54.7%, 81.3% and 43.9% respectively on the way-in in the afternoon peak hour. Study area no.2 contributes considerably to the other corridors such as Kham Thien, Nguyen Thai Hoc and Kim Ma with a contribution of about 68.7%, 42.5% and 26.2% respectively on the way-in in the morning and 72.8%, 0% and 37.8% on the way-out in the afternoon.

A set of scenarios for relocation have been constructed. The comparison of traffic volume with road capacity of all main corridors is applied to evaluate the contribution of the selected land-uses to traffic congestion in both morning peak hour and afternoon peak hour as well as after relocation. This is done by applying advanced spatial and network capabilities of GIS. It appears that congestion can be relieved considerably by integration of land-use and transport in combination with good land-use policy of government.

First of all, I am grateful to my supervisors, Dr. Ir. M.H.P. Zuidgeest (First Supervisor) and Ir. M.J.G. Brussel (Second Supervisor) for their advice, encouragement and support during my research. Their advice and constructive criticism lead me on the right track. I always recover full energy after receiving their encouragement which helps me to overcome many difficulties during the analyse process.

Secondly, I would like to express my sincere thanks to the management boards and all staff of Vietnam Railways, Ministry of Science and Technology, Bach Mai hospital, Viet-Duc, C, K hospitals as well as all teachers and students of Polytechnics University, University of Construction and University of Economics for their support and information. Without their support I can not complete my research.

Thirdly, I would like to express my gratitude to my assistants: Ms. Dao Thi Anh Chuc, Ms. Chu Thi Nguyet Nga, Ms. Do Thi Dieu Thuy, Ms. Dang Thi Phuong Quynh, Ms. Ta Thi Huyen, Ms. Duong Thi Ha, Ms. Ngo Thi Hong, Mr. Nguyen Anh Phong and Mr. Vu Dinh Quang who work shoulder to shoulder with me during my fieldwork. Every day, they worked from 6:00 AM till late afternoon for delivering questionnaires and collecting them as well as inputting all information into database.

Next, I would also like to thank Mr. Tran Nguyen Toan from Government Office of Vietnam, Mr. Bui Dinh Nghi, Mr. Nguyen Duc Duc from Vietnam Railways, Ms. Nguyen Thi Thanh Hoa, Mr. Vo Anh Tuan, Mr. Khuat Viet Hung, Mr. Le Dai Ngoc and Mr. Vu Anh Tuan for their help and providing materials.

I am indebted to Prof. Tran Tuan Hiep-Vice Rector, Prof. Nguyen Quang Toan and Prof. Nguyen Huy Thap from the University of Communications and Transport for supporting me.

Lastly, I want to give my best gratitude to my family and my friends, especially Ms. Chu Thi Chi, Ms. Vu Mai Trang and Mr. Tran Hong Kien who encourage me and give me confidence in difficult moments.

Nguyen Ngoc Quang

1. Introduction

1.1. Background

Transport in itself is a very fundamental need of people, after food and housing, possibly one of the strongest. Transport of goods and people in a city plays an important role, as it functions like the circulation system in a living organism. Urban transport directly affects the economic efficiency of cities and the well-being of their inhabitants. When urban transport is inefficient, it can be a major source of problems for cities and their inhabitants(Orn 2003).

Rapid urbanization and an increase in motorization in developing countries have put high pressure on transport as reported by World Bank "*Most of the cities in the developing countries face severe transport problems. Road congestion is spreading; the movement of people and goods is slowing to a crawl*"(World Bank 1986; Orn 2003).

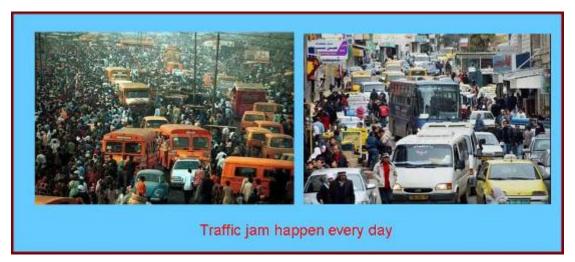

Figure 1.1: Traffic congestion in developing countries (Source: (Square 2003))

"Improved mobility = Improved prosperity" (UITP 2006). But the question for many developing cities is how to relief traffic congestion and improve mobility? The traditional approach to urban transport in the United States and many other cities like Bangkok (Thailand), Jakarta (Indonesia), etc has been always been to *"build away"* the problems by producing more urban roads and highways with multilanes and elevated expressways to favour the movement of vehicles or high-cost public transport systems such as rail-based metros. This strategy seems to be logical, but the lesson drawn is that it is not effective way. Recently, urban planners have realized that infrastructure alone will not solve traffic problems, only through the integration of land-use and transport in combination with promotion of good public transport and restriction of private vehicle use can achieve sustainable transport(DUAP 2001; Sim, Malone et al. 2001; Petersen 2002; Orn 2003; Whitelegg and Haq 2003; Emberger 2005; Lohani 2005; UITP 2006).

Intelligent land use planning plays an important role in coping with traffic congestion and ensuring sustainable transport because spatial distribution of housing, working, shopping, leisure and other activities determines trip frequency, trip distance and modal share. Therefore, by influencing the

spatial structure of activity locations in the urban environment, land use planning can contribute to reduce number of trips, trip lengths and support a high share of "green modes" (public transport, cycling and walking). Petersen (2002) emphasizes that "Without acknowledgement of the interactions between land use planning, urban growth and transport development, no sustainable transport system will emerge, neither with respect to economic nor to social and environmental criteria. Setting priority on road network capacity extensions without a clear vision of spatial development has failed to mitigate congestion everywhere in the world". Therefore, the integration of land use and transport is one of the most important tasks in transport planning in order to achieve sustainable transport. It aims to improve mobility and accessibility for people, services and resources for achieving economic effectiveness and social equity and should be considered carefully in the planning.

The travel of people with a transport mode (bus, walking, cycling) from one place to another through road network involves costs measured in travel time, travel distance or travel fee. These costs cause an impedance or resistance for travel and are used as accessibility indicators. By putting some impedance constraints such as maximum travel time by bus within 30 minutes or walking time less than 15 minutes, we can evaluate how good the spatial distribution of land-uses in combination with transport and indirectly measure the congestion level. A good spatial distribution of land-uses and transport will reduce the number of trips, total trip length or increase the number of people using "green modes" (bus, walking, cycling) and congestion level will be reduced relatively as a consequence. If a service location is not good in term of accessibility, it should be relocated. Recently, this notion has been applied to evaluate the integration of land-use and transport in several researches(Cervero 1988; Aarhus 2000; Hanssen 2000; Sim, Malone et al. 2001; Jong, Geertman et al. 2003; Wee and Maat 2003; Marquez, McNamara et al. 2004; Belal 2006; Geurs 2006)

1.2. Transport issues in Hanoi

Hanoi is the capital of Vietnam, where more than 30 hospitals at national level, more than 2000 government offices with more than 300,000 staff, 112 institutes and more than 60 universities and colleges, 41 vocational schools and 34 technical schools with more than 553,000 students in total are located. Most of them are located in the city centre (M.O.T 2004; M.O.C 2005). With poor and uneven road distribution, just about 1.9% of road area to Hanoi's total land area, in combination with poor public transport and a high share of motorcycle traffic congestion is experienced during peak hours every morning and afternoon.

To cope with traffic congestion, many counter-measures have been applied such as: expanding the existing roads, building new roads, flyovers, enforcing traffic laws, applying traffic signal, improving operation of public transport, etc but the situation has not been improved very much. This situation might be worse with the current figures of economic and population development. Recently, there are many disputes on how to improve mobility for Hanoi people, some ideas are that traffic congestion can not be relieved unless metro lines are built, while others say that traffic congestion can be relieved if some government offices, universities and some hospitals are to be removed out from the city centre(TP 2005). A targeted task of the transport sector is to relieve traffic congestion and improve public transport to meet 30% of the demand by 2010 with the support of a rail-based system (MOT 2004). The main question in this research is whether we can relieve congestion and improve accessibility by relocating some major land-uses?

1.3. Research problem

Traffic congestion in Hanoi, particularly in the city centre, is serious. Several discussed on how to solve the co-exist. One of the ideas is to relocate some major land-uses to the Western part of the city. The effect of this relocation on traffic congestion is however unknown.

Therefore, the main hypothesis in this research is relocation of some major land uses such as government offices, hospitals and universities can relieve the congestion situation and as such improve accessibility.

In this research this hypothesis will be investigated by testing some alternatives of integration of land uses and transport in Hanoi in order to have better mobility for Hanoi people.

1.4. Research objectives

The main objective is to investigate the hypothesis by testing some alternatives of integration of land uses and transport in Hanoi in order to have better mobility for Hanoi people will be tested.

The sub-objectives are:

- To evaluate the current situation of some selected major land-uses in term of how they contribute to the current levels of traffic congestion in Hanoi.
- To test some scenarios of relocation for some selected major land-uses to see if and to what extent they can relieve traffic congestion in Hanoi.

1.5. Key research questions

Some key research questions are addressed as follows:

- How much do the selected land-uses contribute to congestion on corridors and congested roads?
- Can traffic congestion situation be relieved by expanding roads only?
- Can we relieve congestion by relocating the selected major land-uses? And how much can we achieve?

1.6. Study area

The main study area is in the city centre of Hanoi-Vietnam, particularly the part within the ring road no. 2, where most government offices, universities, and hospitals are located and where congestion is very serious. The main study area is indicated within bold line in figure 1.2 below. Two specific study areas are proposed.

Study area no.1 is Bach Mai area where three big universities (Polytechnics, Construction, and Economics universities) and a group of hospitals including Bach Mai hospital. Some corridors near-by this area are suffering severe traffic congestion during peak hours every day such as Chua Boc, Truong Chinh, and Thai Ha streets.

Study area no. 2 is the urban core (Hoan Kiem district) where many government offices are located. Huge of people is observed on some corridors leading to this area every morning on the way-in and on the reverse direction in the afternoon such as Kham Thien, Kim Ma, Nguyen Thai Hoc, Ba Trieu, Pho Hue, Chuong Duong.

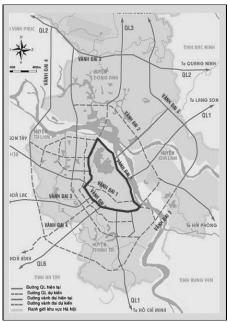

Figure 1.2: Study area

1.7. Conceptual framework

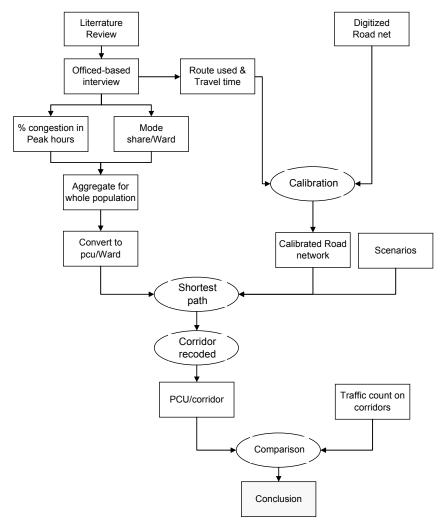

Figure 1.3: Conceptual framework

Based on literature, an office-based interview method was selected to get information on trip origins, transport mode, travel time, route used and some other important information on social-economic characteristic of trip.

Based on the information extracted from the survey, the road network is calibrated before conducting analyses.

From interview responses, the percentage of people who travel during peak hours as well as the mode share per commune are calculated and then converted into pcu (passenger car unit) for comparison purpose. A shortest path algorithm is then applied to record corridors used when a person is going from one commune to the destination. And finally, the comparison is made between the existing situation and scenarios based on the traffic count on corridors, congestion level and congestion mark.

Because a transport model, nor a full-fledged transport study, is available for Hanoi, this research focuses on information on travel patterns of those working or visiting the selected land-uses. Their travel patterns reveal important information on the contribution of the land-uses to the congestion situation in Hanoi.

Note: In this research, all green modes like walking, cycling and going by bus are considered not contribute to traffic congestion. Only motorcycle and car is taken into account.

1.8. Structure of the research

Chapter 1: Introduction

This chapter contains the background of the research, research problem, research objectives, research questions, and research methodology.

Chapter 2: Interaction between land-use and transport

This chapter will give some ideas of the interaction between land use and transport, accessibility indicators.

Chapter 3: Hanoi: An introduction

This chapter will give some background information about Hanoi, including population, distribution of some major land-uses, the existing road network, the existing public transport system, the congestion situation, the modal share, and reviews some recent studies for Hanoi transport and their short comings.

Chapter 4: Data collection and data preparation

This chapter will discuss the data requirements, data collection, fieldwork, and data preparation.

Chapter 5: Contribution to congestion of the selected land-uses

This chapter will evaluate the selected major land-uses in term of their contribution to congestion on the different main corridors and congested roads.

Chapter 6: Scenarios of relocating some major land uses

In this chapter, some selected alternatives of land use and transport will be tested.

Chapter 7: Conclusions and Recommendations

This chapter gives some conclusions and recommendations for further research.

1.9. Discussion on newspapers on the relocation of some major landuses

Relocation of land-uses is an important discussion currently held in Hanoi. Here is a brief summary of an article from the electronic newspaper Hanoinet from late 2005 (http://hinet.net.vn/news), indicating the importance of this research.

What is the solution for transport in Hanoi: build new road or just expand the existing roads?

Summary:

- Inner districts of Hanoi have an area of about 110km2 with total road network of about 400km long (6 km2) equivalent to 6% of urban land. The road network is uneven distributed: the road density of the old squared streets is about 12%, while the other area is just about 5%.
- According to some transport experts, in order to deal with traffic congestion, Hanoi needs to increase the road density up to 20% of urban land. But due to very densely population, Hanoi needs at least US\$14 billion just for land clearance and the total investment for road construction is about US\$17 billion. And the investment will be much higher if metro lines are built.
- What is the best solution for transport in Hanoi? There are some different ideas as follows:
 - ✓ The first idea is to build good infrastructure together with other social services and low-price houses in outer districts (surrounding the city centre) to attract people to live outside the city centre, while keeping the same conditions of the city centre (within ring road no.2). The advantage of this solution is it reduces the population density inside the city centre and as a result it will reduce traffic congestion. But the disadvantage is that we need long construction time and during this time the traffic congestion situation in Hanoi is the unchanged.
 - ✓ The second solution is to expand and build new roads in Hanoi and at the same time to build new urban areas with good infrastructure as in solution 1. This solution has the disadvantage that it is an expensive investment and that actually people do not want to live far from the city centre if the transport is already improved.

The weakness of both solutions is the government's offices and other organizations like hospitals, universities are still located inside the city centre. Therefore the traffic congestion will not be solved or even become worst because the travel distance is longer. That will be the main reason why people do not want to live far from the city centre. The solution is to relocate government's offices and other organizations outside the city centre.

- ✓ The third idea is to remove (relocate) government's offices out of Hanoi centre. According to economic experts, with US\$15 billion, Hanoi can build new urban centre for education, politics, and finance, etc activities with very good infrastructure outside ring road no.3. And if organizations like Polytechnics University, Construction University, and Economics University and some hospital like Bach Mai hospital, Viet_Duc hospital, K hospital, and C hospital are removed from Hanoi, the transport situation might be better. And on the other side we can have a chance to build better and up-to-date infrastructure for these organizations.
- Finally, to reduce traffic congestion in Hanoi both solutions have the same idea as to reduce population density inside the city centre. But in order to reduce population density and attract people to live outside Hanoi, beside good infrastructure, low-price houses and other social services for people we need to relocate government's offices and other organizations outside the city centre. But how to relocate, government should have good and clear policy. (TP)

(Note: For the original article in Vietnamese version, please refer to Appendix A)

2. Interaction between land use and transport

2.1. Urban transport in developing countries

Transport is an activity that people have engaged in since the beginning of humanity. Transport helps people to reach different places, where they can perform their activities and enable the movement of goods inside cities. Generally urban transport can be defined as the movement of people and goods in urban areas. This movement takes place in space and time. In "space" as activities are located in different land uses of the city and people have to move from one land-use location to another; in "time" as activities are often constrained by time, which means that people should travel to these activities at a certain time of the day. Besides these spatial and temporal characteristics, the movements are also determined by socio-economic, demographic and cultural characteristics of the city. These characteristics create the demand for travel and define where people travel and what modes of transport they use for travelling. This demand can be satisfied if an adequate transport system is provided (Belal 2006). Traffic congestion will happen when the travel demand is far beyond the capacity of the transport system at a certain time of the day.

Rapid urbanization and booming of motorized vehicles in developing countries have put high pressure on the urban transport systems. Over the last two decades, Asian cities have been suffering severe traffic congestion due to dramatic increases in motor vehicle growth rates. And traffic congestion is experienced almost every day. The average speed of motor vehicles during peak hours in many cities is just between 5-10km/h(World Bank 1986; Orn 2003; Whitelegg and Haq 2003; Belal 2006). This situation not only reduces greatly the effectiveness of all social activities, impede economic development in the city, but also destroys the living quality of inhabitants in the city and creates a polluted environment(Whitelegg and Haq 2003).

One of the challenges for urban planners in developing countries is to make cities sustainable and equitable with good accessibility through an efficient transport system without congestion. The variety of measures that have been used to alleviate traffic congestion in cities can generally be classified into the integration of land use and transport planning on the one hand, and demand management instruments on the other. The first group of measures, based on the premise that there is a close link between land use activities and the number of trips generated, is aimed at reducing the amount of travel (trip lengths and trip generation). The second group of measures, however, aims to reduce reliance on the car, and for example promote the use of public transport. (Sim, Malone et al. 2001).

Various measures have been tried such as expanding existing roads, building new roads, improving public transport including metros, traffic restriction, improving traffic signals and traffic control, congestion price, parking fee, road pricing, etc. but with little success. Recently, urban planners have realized that infrastructure alone will not solve traffic problems, and only through integration of land-use and transport in combination with promotion of good public transport and restriction of private vehicle use can achieve the targeted task (Sim, Malone et al. 2001; Orn 2003; Whitelegg and Haq 2003; Emberger 2005; UITP 2006). Transport and land-use are two key elements for achieving sustainability in an urban context. In the past, land-use and transport were treated separately-their

interdependence was not realized in full. Recently, it is recognized that sustainable development can only be achieved when transport and land-use are treated simultaneously (Emberger 2005).

2.2. Interaction between land use and transport

Integrated land-use and transport planning are essential for environmentally, socially and economically sustainable urban development as observed in Peterson (2002).

In transport analysis, a city is usually modeled as a collection of separate homogenous islands (zones) that are most commonly called Traffic Analysis Zones (TAZ). These zones are areas where travel originates (origins) and terminates (destination). The transport network is the "bridge" that links these zones(Belal 2006).

As mentioned above, the movement takes place in space and time, from one land-use location to another at a certain time of the day. Most trips are made because people want or have to carry out activities. Land-use is spatial distribution of activities. This distribution generates traffic for people move from one activity to another. Travel demand depends on the utility of the activity, on the one hand, and on the aggregate costs to reach the destination, on the other hand. The aggregate costs measured in time, money, and efforts needed to cover the distance are usually expressed as transport resistance or impedance(Blijie and Bok 2002; Wee and Maat 2003).

According to Bert van Wee and Kees Maat with a given population size and demographic characteristics, the total volume of passenger transport and the split transport modes depend on the locations of human activities (such as education, working, shopping, etc), the needs and desires of people and the transport resistances. The travel needs and desires of people (usually expressed as total travel distance or number of trips) relates to socio-economic and cultural characteristics, while transport resistances relate to financial factors, travel time, comfort and reliability of transport mode. The aggregate costs needed to cover the distance are not only determined by the quality of the transport system but also by the characteristics of the spatial structure surrounding the sites where the activities take place. The spatial structure determines the generalized costs between the activities, as well as the ease of access to the various traffic modes(Wee and Maat 2003).

The relationship between activity location, travel need and transport resistance is depicted below.

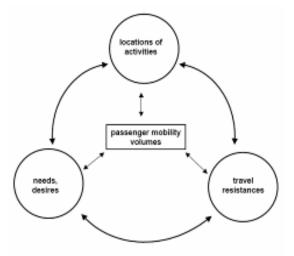

Figure 2.1: Relationship between activity locations, travel need and transport resistance (Adopted from (Wee and Maat 2003))

These three factors have a strong relation. Any change of one factor among the three might lead to the change of the performance of the whole system. Change in land use patterns might change transport resistance between certain locations and might reduce travel needs also; good planned activity locations might contribute greatly to relief of traffic congestion, reducing travel time/distance as well as improving environment (Wee and Maat 2003).

From literature, there are two main directions in the integration of land-use and transport: that is mixed land-uses and relocation some major land uses such as office, hospital, etc. for example out of the city centre. The purpose of integrating land-use and transport is to move local and regional spatial structures in the direction of:

- Reducing the demand for transport (including number of trip and travel time/distance),
- Increasing the choice of available transport and reducing dependence on motorized mode,
- Improving accessibility to jobs, and public services
- Supporting the efficient and viable operation of public transport services, walking and cycling
- Enhancing healthy conditions for living.

In general, the integration of land-uses and transport contributes greatly to relief traffic congestion, reduction private automobile dependence and improvement of the urban environment (DUAP 2001; Sim, Malone et al. 2001; Petersen 2002; Wee and Maat 2003; Whitelegg and Haq 2003; Geurs 2006).

2.2.1. Mixed land-uses

Many authors agree that higher densities, and mixed land-uses that are associated with them, shorten the length of trips by all modes, for example making walking and cycling attractive for more trips and create sufficient concentrations of activities for an effective, frequent public transport service(Cervero 1988; Sim, Malone et al. 2001; Petersen 2002; Whitelegg and Haq 2003)

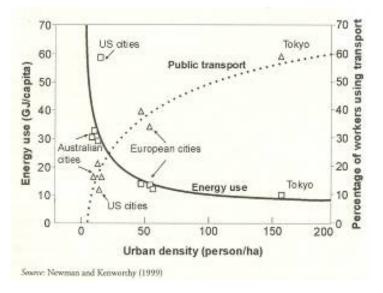

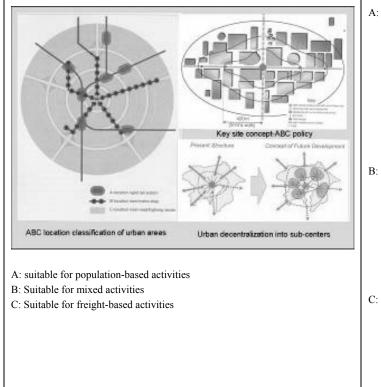

Figure 2.2: Energy used and urban density(Petersen 2002)

Anyway, there is no fixed number for good urban density. It depends very much on how well the spatial structure is organized, relative separation in location between residential area and activity locations like schools, hospitals, business area, and highly depends on culture as well as other factors. Therefore, it can explain for example why in Hong Kong, with its very high urban density

(300 persons/ha), there is hardly congestion ; but can not explain why Bangkok with its higher urban density (162 persons/ha) than Singapore (88 person/ha) has a much worse traffic situation(Whitelegg and Haq 2003). We can only know that mixed land-uses with well structured high density urban areas can reduce total trip length, consumed energy used for transport, and increase effectiveness of public transport as well as encourage walking and cycling within urban area.

In Hanoi, almost all government offices, business centres and many large hospitals are located in the city centre (within ring road no.1); some other hospitals and universities are located within ring road no.1 and no.2 while main labour forces are living outside ring road no.2 (in between ring road no.2 and no.3). This is because the centralized ideal is *"Thu Nhat Kinh Ky, thu nhi pho Hien"* which means all the best and highest quality services are located within centre area of the capital city was predominant in previous urban planning. That is why the number of universities, colleges, institutes as well as hospitals in Hanoi account for 50% of the whole country. It makes a big gap in both service quality and quantity between Hanoi and other areas surround. Therefore, a great amount of labour force, students and patients from half of the country flock into Hanoi for working, study and treatment. That is why we have experienced a huge flow of people coming in the city centre every morning and return in reverse direction in the afternoon; And together with high rate of motorcycles (1.9 millions of motorcycles account for 74% of trip demand) and poor public transport running on quite low density of road network (6% of urban land) congestion happens during peak hours almost every morning and afternoon(MOT 2004; HAIDEP 2005).

But how to evaluate the quality of mixed land-uses, what are appropriate criteria/indicators for evaluation of mixed land-uses? Eventually residents tend to move to more accessible locations (Blijie and Bok 2002). Therefore, a good indicator recently used for assessment of mixed landuses is accessibility. As indicated by Banister(2002), "Underlying much of the debate on sustainable development is the importance of accessibility or the ability to reach a range of services and facilities easily. This simple concept is at the heart of much planning and transport thinking as its intention is to keep travel distance as short as possible. One of the fundamental axioms of transport planning is that people do not like travelling, and they only travel because the benefit received at the destination (work, education) more than outweigh the cost (i.e. time and money) of getting there. An important corollary of the axiom is that if journey distances are short, then people are more likely to use "green modes" of transport (walk, cycle) or public transport". Therefore, based on this notion we can somewhat know how well the spatial distribution and transport system are organized. For example, according to recommendation of Department of Urban Affair and Planning of Sydney, Australia every household should be substantially within 800m total walking distance from an existing or programmed rail station (or equivalent mass transit mode), served at least every 15 minutes or within 400m walking distance of a bus route at least every 30 minutes(DUAP 2001). Or the relation between quality of location and transport demand is studied comprehensively in the well-known Dutch ABC-Planning, in which cities with more than 100,000 inhabitants are required to prepare land use plans allocating the area into three different categories A, B and C with all the classes A,B,C explained in figure 2.3.

A: Locations that are easily accessible to local, regional and national public transport (area around public transport junction); share of commuting by car should be under 10-20%. These locations are typically suitable for offices with a large number of employees and many visitors. The sites have to be within 600m of a national or regional railway interchange or within 400m of a high quality tram or bus stop; not more than 10 minutes ride bicycle from a national railway station and a good connection to park & ride facilities.

- B: These locations are characteristically chosen for offices and institutions with a large number of employees, which depend partly on car journeys for professional reasons. Such sites are within 400m of a high quality tram or bus stop and no more than 5 minutes ride from a regional railway station. In addition, they have to be within 400m of a main road connected to a national highway; share of commuting by car is under 35%.
- C: These locations are suitable for car-dependent companies like factories, industries. These sites are within 1000m of a direct connection to a national highway and normally situated in the outskirts of metropolitan areas.

Figure 2.3: Dutch ABC planning (Source: (Petersen 2002)

According to this planning concept, the best location (in green area) attracting large numbers of travellers is within walking distance around a rail station also served by major bus routes. Increasing distances from that spot will be less attractive for transit passengers, and travellers will increasingly tend to use private cars and taxis. This ABC scheme and key site concept should be combined with general urban development paradigm to avoid traffic problems such as congestion, emission hot spots in high concentrated centre area, especially when housing spreads in the outskirts of the cities, and workplaces as well as shopping facilities located in the city centre. In this situation, sub-centres within the city boundaries should be formed to reduce traffic pressure on the roads leading to the main centre and average trip distances as well as number of trips by homogenous distribution of activities in the whole city(Petersen 2002). It means that some major services/organizations should be relocated as called "*decentralization*" in many other literatures or newly set up outside the city centre (Naess and Sandberg 1996; Sim, Malone et al. 2001; Whitelegg and Haq 2003).

Many cities in the world, especially in the Netherlands, have provided good practice examples, where integration of land-use and transport in planning with consideration of accessibility notion can result in a reduction of car use, improved public transport use, walking and cycling and a better quality of life such as in Groningen city, The Netherlands, where since 1990 already, got success with 48% of all trips within the city were by bicycle, 17% by foot, 5% by public transport and just 30% by car; Houten in the Netherlands has developed a comprehensive bicycle/pedestrian network and cut car trips per household by 25%; Manchester (UK) the Metrolink tram has taken up to 50% of car journey off roads in the area it serves. It has replaced over 1 million car journeys into the city centre each year; Portland, Oregon (USA) 40% of commuters using public transport; Curitiba, Botaga (Colombia) and Copenhagen (Denmark) (Whitelegg and Haq 2003); or

Singapore with the most reliable and efficient transport system in the world "*The key to* Singapore's success lies in its comprehensive and highly coordinated land transport policy, which combines the integration of land use and transport planning with demand management measures".(Sim, Malone et al. 2001)

2.2.2. Relocating major land uses

Service location relates to organization/ service effectiveness it self and relates to effectiveness of society through the effect to accessibility of its staffs and customers, affect to traffic on road network. Traffic congestion can be relieved or increased with consideration of service/organization location or relocating them(Jong, Geertman et al. 2003). Therefore, locations of activities that lead to traffic congestion or reducing accessibility of attendants (staffs, customers), or that increase private vehicle use dependence or reduce effectiveness of activities themselves and effectiveness of society, should be relocated. The indicators used for measuring effectiveness of relocation usually are total number of trips, total trip length or fuel consumption, mode share (percentage of people shifting from private vehicle use to "green modes" like walking, cycling or public transport) and change in traffic volume on congested roads compared with before relocation(Cervero 1988; Naess and Sandberg 1996; Aarhus 2000; Wee 2000; Peuralahti 2003; Whitelegg and Haq 2003).

Anyway, there are many disputes in literature whether a decentralized patterns of job sites outside the city centre or whether a high concentration of jobs and activities in the inner city will lead to the shortest trip lengths and thus minimize total volume of transport related to journeys to work. Some authors ague for example that high concentration of activities and jobs in the inner city will reduce number of trips and travel distances. Therefore, relocation of organizations from inner city to suburban area would result in a higher share of number of trips and travel length of employee to work (Naess and Sandberg 1996; Kadesh and Roach 1997; Aarhus 2000; Hanssen 2000; Peuralahti 2003; Marquez, McNamara et al. 2004).

Traffic is not only affected by land use but also by public transport, parking policy, etc. Changes in land-use patterns might change in transport resistance between certain locations. Many cases of office relocation land use policy have failed in reducing trip volume and travel distance such as: the suburbanization of offices in the Netherlands in the 1980s resulted in longer travel times by public transport and more congestion on motorways. It also increased car ownership because of the poor public transport accessibility of the new office locations; relocation of the Utrecht Medical Centre (UMC), for example, done by the Geographic Institute of Utrecht University in 1990 reveals that the car use increased from 58% to 72% after the hospital was relocated kilometres away from Utrecht central railway station as compared to the previous location, which was just within walking distance from the railway station (Wee and Maat 2003); a case study of firm relocation in Oslo, Norway shows that car use increased (from 25% to 41%), average travel time increased by 7 minutes while the use of public transport was reduced from 61% to 46% despite the new location being well served by public transport(Hanssen 2000). Besides these failures, many success cases have been recorded such as: a survey carried out in 1979 on occasion of relocation of a department of the Province of South Holland with the moved distance of just a couple of hundred meters to a location very close to the Central Station in The Hague revealed that the car use was found to be halves: from 37% to 19%, while public transport use doubled: from 34% to 70%; the relocation of the Ministry of Housing, Spatial Planning and the Environment of Netherlands in 1992 to new location with highly accessible by public transport, just beside the

Central Station in The Hague, got achievement in reducing the car use from 41 to 4% with shorter total travel distance(Wee and Maat 2003); the decentralization's strategy of commercial activities to regional centres and sub-regional centres to relieve congestion in the CBD of Tampines Regional Centre, Singapore provides a good example of the integration of land use and transport planning that give the opportunity to work closer to home and minimize travel expenses and time(Sim, Malone et al. 2001).

These examples reveal that the main reasons of these failures are firms relocated from locations with respectively good accessibility to locations with relatively poor public transport access and the provision of ample free car parking in the new locations.

The main method of relocation studies is in comparing the situation before and after the organization was relocated by interview for example, surveys or making scenarios with some indicators (Naess and Sandberg 1996; Aarhus 2000; Hanssen 2000; Peuralahti 2003; Kirca and Tabalu 2004; Marquez, McNamara et al. 2004).

The suitable indicators selected for Hanoi case study should be total trip length and change in traffic volume on congested roads and the suitable method would be to compare scenarios of before and after relocation, as the real relocation has not been done yet.

2.3. Conclusions

Recently, urban planners have recognized that transport and land-use are two key elements for achieving sustainability in an urban context and integration of land-use and transport with aims at reducing the amount of travel can help to alleviate traffic congestion.

There are two main streams in the integration of land-use and transport: that is mixed land-uses and relocation of some major land-uses such as hospitals, offices for example out of the city centre. The main purpose of integrating land-use and transport is to reduce the travel demand including reduced numbers of trips, travel time, travel distance and to encourage people shifting from private vehicle ownership to green modes including walking, cycling and bus by improving accessibility to job site and other public services.

The indicators used for measuring effectiveness of relocation usually are total number of trips, total trip length or fuel consumption, mode share (percentage of people shifting from private vehicle use to "green modes" like walking, cycling or public transport) and change in traffic volume on congested roads compared with before relocation.

The main method of relocation studies is comparing the situation before and after the organization is relocated by interview survey or scenarios studies with some transport indicators

In this research, some scenarios will be constructed to compare the current situation and possible future scenarios with an indicator for traffic volume on some corridors and congested roads.

3. Hanoi city: An introduction

This chapter will give you an overview of Hanoi city, distribution of population and some major land uses; Hanoi transport and current situation of traffic congestion as well as some missing in the recent studies for Hanoi transport.

3.1. Brief introduction on Hanoi city

Hanoi, capital city of Vietnam, is located in the North of Vietnam. Hanoi is not only the capital of the nation but is also its political and cultural hub, as well as the science, education, and economic centre. It plays a leading role in the region being the gateway to national and international markets. In addition, it is an attractive city both to tourist and residents due to the preservation of its beautiful and cultural surroundings and the stable political situation and low crime figures. (JICA August, 2006).

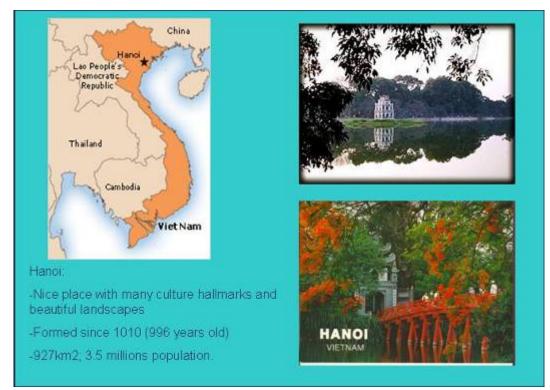

Figure 3.1: Hanoi-Capital city of Vietnam

3.2. Hanoi population distribution

Since the Doi Moi policy was introduced in 1986, Vietnam's economy has grown rapidly and Hanoi has experienced notable urbanization. During the last decade, Hanoi has grown rapidly in many aspects. Its population has increase at a rate of nearly 2.9% per year. As of 2005, Hanoi has a population of 3,183,000, 62.6% of which resided in urbanized areas. Although such rapid population growth can be seen in the entire city, it is particularly significant in the city's urban

fringe districts like Thanh Xuan, Cau Giay, Hoang Mai and Tu Liem districts(JICA August, 2006) (see table 3.1)

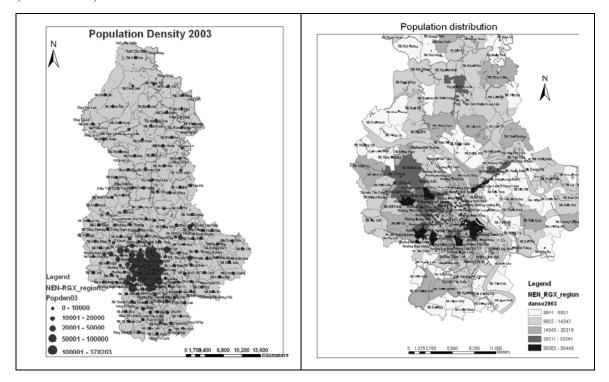

Figure 3.2: Distribution of population in Hanoi

| | | | Popula | tion (1000 p | people) | | Annual | Popula | tion Densit | y, 2005 |

Hanoi's population by District

Table 3.1: Population by district in Hanoi

Hanoi's distinguishing characteristic is the compactness of its urban area with a high population density. While its urban core which comprises four districts only occupies 35km2, it has a population density of 316 persons/ha. In residential areas, the density increases to 399 persons/ha.

In the urban fringe, population density is moderate at 62 persons/ha, except in Thanh Xuan, which has 215 persons/ha and Cau Giay which has 142 persons/ha. However, the density in residential areas sharply increases to 111 persons/ha in the urban fringe. A similar pattern is also seen in suburban areas (JICA August, 2006).

The changes in the urban environment in Hanoi have occurred rapidly and drastically. Inflow of population from rural areas and other cities has been more than expected, probably due to the wider employment opportunities and higher education, among other things, offered in the capital city (JICA August, 2006)

Recently, some newly-built residential areas with good infrastructure in the West and the South of the city like Trung Hoa-Nhan Chinh, My Dinh, Nam Trung Yen, Dinh Cong and Linh Dam as shown in the figure below have attracted quite a lot of people out from the city centre for living.

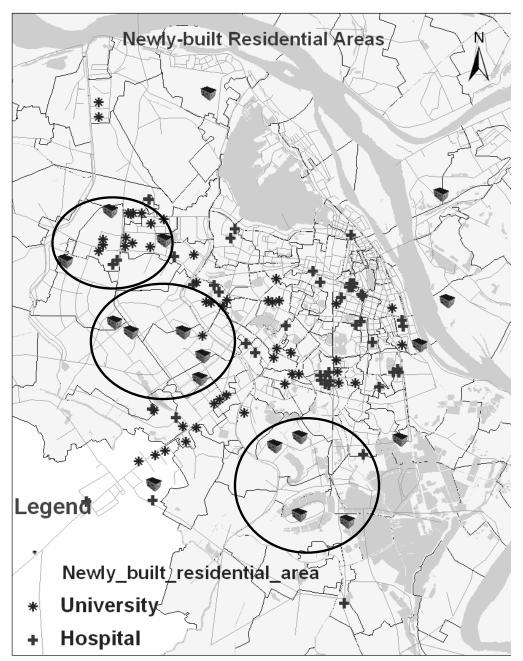

Figure 3.3: Newly-built residential areas

3.3. Distribution of some major land uses

According to the survey of administration offices and business enterprises of Hanoi in 2002, in urban core (Hoan Kiem district) there are 464 administration offices with 23,028 staff in among them 161 offices at national level with 16,218 staffs, and 12,196 business enterprises with total labour of 22,030 people; Ba Dinh district has 1.279 administration offices with 98,976 staffs in total among them 1,083 offices at national level with number of staff of 93,331 people. That is why Ba Dinh district is always considered as administration district and Hoan Kiem district is considered as business district (G.D.S 2003; pp33,48,51).

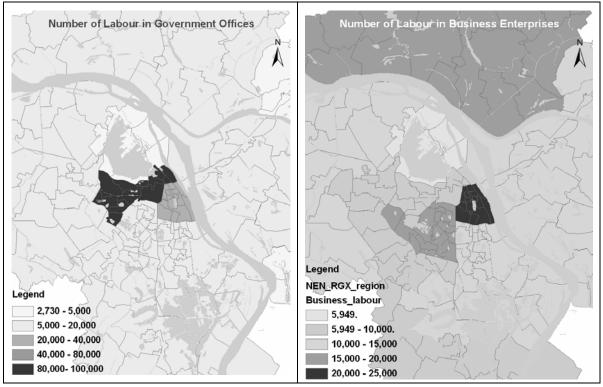

Figure 3.4: Number of labour in administration offices and business enterprises

 Table 3.2: Number of unit and labour in administration offices and business enterprises
 Source:(G.D.S 2003)

Besides that according to the Brief Report on Construction Master Plan for Hanoi Region in 2005, Hanoi has 31 hospitals at national level, more than 63 universities, colleges and vocational colleges with more than 553,000 students in total. Most of them are located within the city centre(M.O.C 2005). It can be seen clearly the uneven distribution of these basic facilities in the figure 3.3 and 3.5 below.

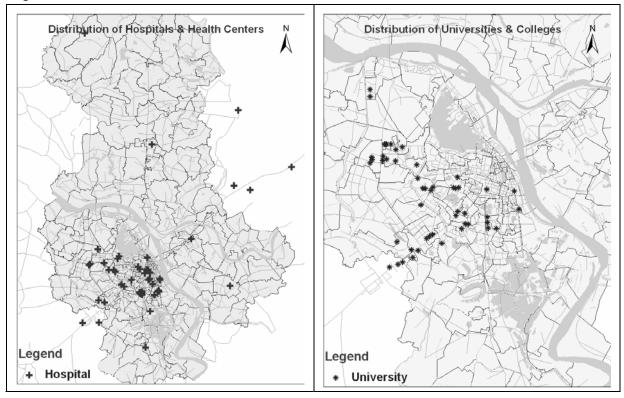

Figure 3.5: Distribution of hospitals

Land-use patterns highlight the fact that the main economic and social functions are highly concentrated in the urban core districts even through their actual land size is very small (JICA August, 2006).

This uneven distribution has put high pressure on urban infrastructure and other urban services.

3.4. Hanoi transport

3.4.1. Characteristics of Hanoi road network

Hanoi has a road length of 624km. The ratio of road area to Hanoi's total land area is 1.9% which is absolutely low compared to major cities in other countries. It is road system is densely developed in urban areas, and it is less dense in rural areas, causing unequal level of accessibility within Hanoi. The city's road network basically consists of radial and ring roads. The radial road network is connected directly to the regional primary road network. It has been observed that the road design standard is often inconsistent with the road function, which, among others, causes "missing links" in the road network, e.g. arterial roads suddenly becoming narrow or interrupted at many places (JICA August, 2006).

Before 2003 when SEA Games were held in Vietnam, a number of road projects were completed in Hanoi, particularly in the west side of central Hanoi where the main stadium was located. After 2003, however, the main focus of road development shifted to the completion of Ring Road (RR) no.2, no.3, and no. 2.5 (HAIDEP 2005). In the city centre, it is very difficult to expand a road due to high density of residential area and high cost for land acquisition. It can be seen in the figure below.

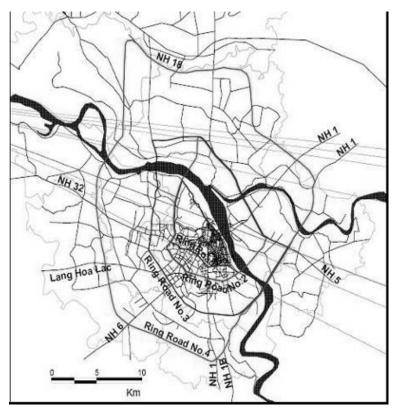

Figure 3.6: Road distribution in Hanoi. Source: (HAIDEP 2005)

Table 5.9.1 Road Development Indicators in Hanoi's Urban and Rural Areas

| | · , | (2003) | Length (km) | Urban Road Area (km ²) | Road Service Level ¹⁾ | Road Density ²⁾ | Road Ratio ³⁾ |

ity: RD(km/km²) =L/A c: RR=RA/A

3.4.2. Transport in Hanoi

Motorization: Along with its population growth, vehicle ownership has sharply increased particularly that of motorcycle. As of 2005, there are 164 thousand cars and 1.566 thousand motorcycles in Hanoi City, increasing at an annual growth rate of 11.1% and 14.8% respectively. Of the total household, 84% own a motorcycle, of which 40% have more than two. Although car ownership is still low at 1.6% of the total population in Hanoi, this figure has increased rapidly, posing a threat to smooth traffic flow in some locations. Rapid economic growth, at a rate of 11% per year, is expected to further accelerate ownership of private vehicles such as motorcycles and cars (JICA August, 2006).

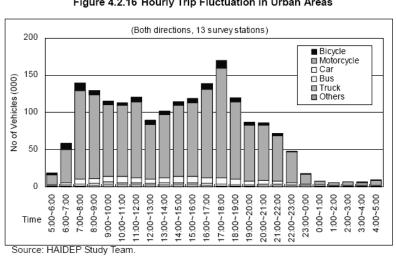

Public transport: Hanoi achieved an initial success in the revitalization of bus services through modernization, with the share of bus in terms of person trips increasing to about 7% of the total in 2005 from a very dismal 1-2% in the previous 5 years. Anyway, the share in total urban transport demand is still insignificant(JICA August, 2006).

Other transports: "Railway services only operate on long-distance routes, with limited efficiency, poor infrastructure facilities and connectivity. River transport is also limited despite the high density of rivers and water channels"(JICA August, 2006)

One important characteristics of Hanoi transport is mixed traffic with very high share of motorcycle. The collapse of public transport in 1989 in combination with a mushrooming motorcycle ownership, led to the strange situation where "Hanoi found itself with the lowest public transport usage and the highest percentage of private transport of all Asian capitals"(HAIDEP 2005)

3.4.3. Traffic congestion in Hanoi

Due to the poor road infrastructure while almost all social activities happens in the city centre in combination with poor public transport services and high share of motorcycle, traffic congestion is experience almost every morning and afternoon peak hours. The morning peak is from 7:00AM to 8:00 AM, the afternoon peak is from 17:00 PM to 18:00 PM

Note: Total traffic volume of 13 survey stations

Figure 3.7: Trip Fluctuation in Urban Areas (HAIDEP 2005)

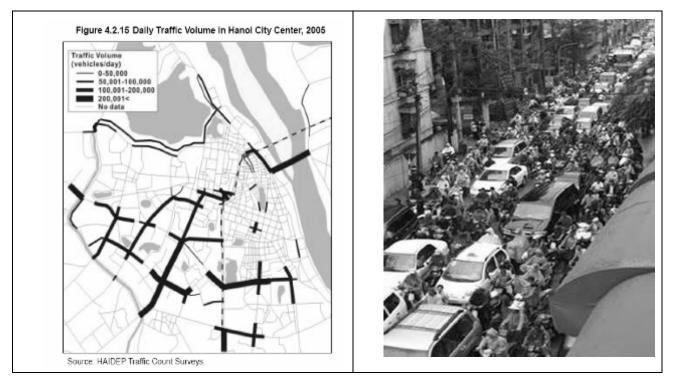

Figure 3.8: Traffic congestion in Hanoi

3.5. Recent studies on Hanoi transport & their shortcomings

Recently, there are two important studies relating to Hanoi transport. The first one is Hanoi Transport Development Master Plan for 2020 prepared by Transport Engineering and Design Incorporation (TEDI) in 2004. The second one is the Hanoi Integrated Development and Environmental Program (HAIDEP) under JICA project in 2006. Both proposals are under review for approval of the Prime Minister.

3.5.1. Transport master plan

According to the Master Plan prepared by TEDI, the development targets are set for public transport projects including satisfying 30% of Hanoi's passenger transport demand by 2010 and 50% by 2020 with the mode share as in the table below.

| | Bicycle | Motorcycle | Car | Bus | Rail-based | Other |
|------|---------|------------|--------|--------|------------|-------|
| 2010 | 13-14% | 34% | 11-12% | 20-22% | 8-10% | 10% |
| 2020 | 10% | 20-24% | 16-19% | 25-30% | 20-25% | 12% |

Table 3.4: Proposed mode share by TEDI (M.O.T 2004; table 8.6, pp8-19)

The followings objectives are highlighted:

- Provide a transport linkage for new development areas
- Develop the public transport system including an urban rail transit system either at-grade, elevated, or underground.

- Alleviate local congestion and enforce traffic laws
- Construct transport nodes at the intersection of radial and circumferential roads.

The report recommends the use of rail-based transit systems with eight new rail routes either atgrade, elevated, or underground and about 200 km long in total. (M.O.T 2004; HAIDEP 2005).

One major shortcoming in this proposal is that it discourages walking and cycling and mainly support for a rail-based system. In the whole document there is no mention about the abnormal distribution of the major land-uses like hospital, universities and government offices as well as there is no solution to re-distribute these major land-uses and encourage people using green modes like walking and cycling.

3.5.2. HAIDEP study

Next to the study by TEDI, in 2004, the Government of Vietnam requested the Government of Japan to conduct a study on comprehensive urban development to ensure that Vietnam follows an appropriate and a sustainable urban development under the name Hanoi Integrated Development and Environmental Program (HAIDEP).

In the HAIDEP study, they also mentioned integration of land-use but the meaning is on-site improvement of land-use.

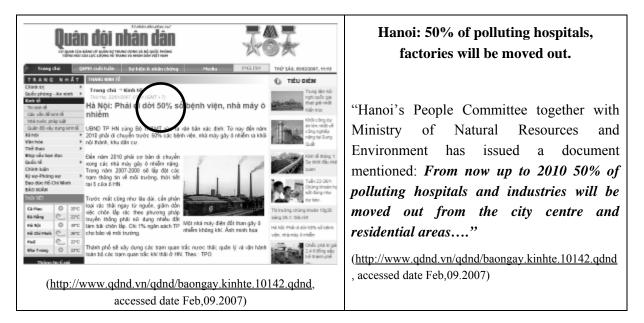

They also mentioned about relocation but just "...Relocate polluting industries..." (JICA August, 2006). There is no mentioned about the distribution of other land-uses like university, hospital and government office.

Besides that they also mentioned that transport infrastructure needs to be improved but in direction of favour mass transit "For large urban areas, such as Hanoi, the only way to effectively meet the transport demand is to provide the city with a high-quality public transport system that is integrated with urban development. The core network will be composed of urban rail metro, and bus rapid transit (BRT)"(JICA August, 2006). There is no mentioned about how to favour and encourage people using other green modes like walking, cycling and bus. However, "building a good public transport system is not an easy task; it requires large amounts of funds as well as operation and management capacities" (JICA August, 2006)

In general, in HAIDEP study, there is no mention about redistribution or relocation of the existing major land-uses like hospital, universities and government offices to relief traffic congestion, reduce number of trip; reduce trip length as well as improve accessibility to encourage number of people shifting to green modes.

3.6. Government policy

Recently, government has a policy to expand the city to the West direction (Ha Tay, Xuan Mai, Hoa Lac, Ba Vi, Son Tay and to the West-North direction (Soc Son, Xuan Hoa, Phuc Yen) (M.O.T 2004; pp6-1). In early 2007, information appeared on newspaper that Hanoi's People Committee has decided to move 50% of polluting hospitals and industries out from the city centre and residential areas before 2010.

3.7. Hanoi's vision

The vision and goals for Hanoi are interlinked with the fact that it is the nation's capital and as such, it should be in the forefront of Vietnam's march toward future growth and the anchor for its identity as a proud and robust nation. This is rightly stated in the vision for Hanoi in Order no. 1/2001/L-CTN which reads: "Hanoi must be built as a modern and thriving capital city, symbolizing the whole country, and functioning as a national and regional centre for policy, culture, science, technology, education, economy, and international trade"(*JICA August, 2006*).

And one of the objectives is to provide efficient infrastructure to make it possible for people to commune safely without traffic congestion(JICA August, 2006)

3.8. Conclusions

Poor road infrastructure, poor public transport and uneven distribution of some major land-uses like hospitals, universities and government offices leading to high separation between the trip origin and trip destination in combination with high rate of motorcycle have caused severe traffic congestion in Hanoi.

Both recent studies for Hanoi transport support rail-based system. And there is no mention about how the major land-uses like hospitals, universities and government offices should be redistributed and how much can we achieve by relocating them in terms of relief traffic congestion.

4. Data collection and data preparation

This chapter describes the data collection at field, and data preparation with focus on road network preparation.

4.1. Data requirements

From the conceptual framework in chapter 1 and indicators used as discussed in chapter 2, the following information is necessary to be obtained from the field:

- Transport mode people used,
- Travel time people go from home and return home from work,
- Living address (ward) where people go to/return from our study areas (trip origin),
- Corridors people used,
- General information of organization for aggregate purpose,
- Their intention of relocation and new location, if any.
- Road network data and its information such as road type, road width, number of lane, traffic volume, etc.

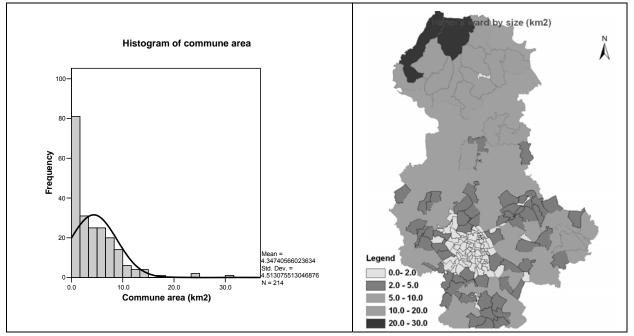

Figure 4.1: Hanoi's ward by size (km2)

One characteristics of Hanoi is that all wards in the city centre have smaller size than the outskirts. In Hanoi, the smallest ward is Tran Hung Dao with an area of 0.059 km2 (or average distance is 136.0 m from ward centre) and largest ward is Bac Son in the outskirt of Hanoi with area of 30,05km2 (or average distance from ward centre is 3.09km), and on average the ward's area is

4.34km2 or average distance from ward centre is 1.17km. Most of Hanoi people are living in the city centre or in fringe wards where the average area is small enough as average area to consider people going from ward centre. Therefore, in this research, the smallest unit used as trip origin is the ward.

4.2. Data collection

4.2.1. Interview form/questionnaires

Since the trip destinations were already decided as mentioned in chapter 1. Therefore, the officebased interview method is selected to get the information on trip origin, transport mode, travel time and corridors used. All these information can be filled very quickly in the short interview forms/questionnaires designed as depicted in a sample below.

Figure 4.2: A sample of questionnaire form

Usually it took less than 5 minutes to fill a form. This strategy is suitable since people are very busy.

4.2.2. Deliver Interview forms and questionnaires

Now the critical matter is how to get information, especially from government staff, doctors, and lecturers since they are very busy. The problem was solved by delivering questionnaires through the administration system of these organizations with the support from management boards. The completed forms were collected one week after delivering. For students, the questionnaires were delivered at classes and collected immediately after 30 minutes from class representatives. The classes were randomly selected and the questionnaires were delivered for all morning class, afternoon classes and night classes. For patients, there is no other way than interview directly with the help of 8 assistants. Finally, 5,561 completed questionnaire forms were collected. The result is summarized in table 4.1, 4.2, 4.3.

Figure 4.3: Interview at hospitals

After collecting the completed forms, all information from questionnaires was input in database immediately by assistant staff. All completed forms were coded and numbered as seen in figure 4.1 above before inputting in database.

4.2.3. Interview management boards

The management boards were interviewed to get general information of these organizations for aggregate purpose and to get information on their intention of relocation, location of new base and solution of relocation, if any. The interview reveals that all the existing bases are overloaded and so narrow that some of them already have the intention to relocate to new bases; some others also have intention to move but still have no idea where to move. And most of the new locations are planned in the west side of the city, except K hospital to the South. The result is summarized in the table 4.1, 4.2, 4.3 below. Later this information will be used to calculate the contribution to congestion on corridors of the whole population of these land-uses in chapter 5 and used to construct scenarios in chapter 6.

Table 4.3: Result of survey at government offices

4.2.4. Traffic count at cordons

Figure 4.4: Traffic count at cordons

In order to analyze the attraction of these organizations, the traffic counts at cordons method were applied. The traffic count was done for all transport means at all gates of these organizations. The traffic count was usually done from 6:00 or 6:30 AM till 9:00 AM in the morning and from 16:00 PM till 18:30PM. The survey reveals that hospitals are very attractive and the busiest time is from 7:00 AM to 8:00AM in the morning. For example till 9:00AM already has almost 9,000 trips going in Bach Mai hospital. Beside that the high rate of motorcycle can also be seen in an example below.

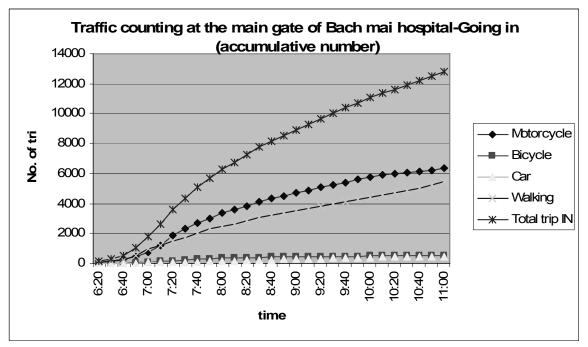

Figure 4.5: Result of traffic count at cordons

4.2.5. Measuring travel speed on some corridors

The travel time by motorcycle on some corridors was done. The purposes are:

- To evaluate and decide peak hours.
- To calculate average travel speed of the traffic flow on corridors in Non-peak and in Peak hours. This information will be used for calibration of road network later.

The survey was done by recording the travel time by motorcycle on one corridor before and after expected peak hours, usually from 6:30 AM till 11:00 AM and from 16:00PM till 19:00 PM. After that the travel speed was calculated by dividing travel length to travel time and then draw on graph as an example below. The survey was also done for both the way-in and the way-out.

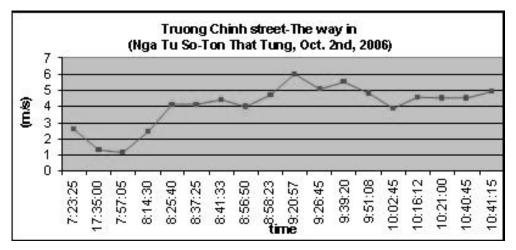

Figure 4.6: Travel speed on some corridors-Morning peak

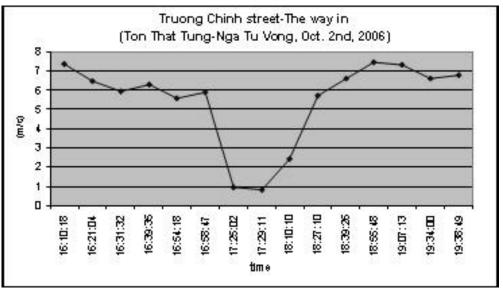

Figure 4.7: Travel speed on corridors-Afternoon peak

The survey reveals that:

- The morning peak is from 7:00AM to 8:00 AM, afternoon peak is from 17:00PM to 18:00PM,
- The most congested corridor is Truong Chinh Street, especially on the way-in in the afternoon.
- The average speed in non-peak hour is from 16km/h to 22km/h depending on the corridor. This information will be used for road network preparation later.

4.2.6. Collection of secondary data

Besides that some secondary data and related documents were collected:

- Ward's boundary in MapInfo format
- Statistics data for aggregation purpose
- Paper maps of Hanoi road network and Bus network.
- Report on current condition of road network from Public Work Service (2006)
- HAIDEP project documents, Transport Development Master Plan for 2020 by TEDI and some other related documents.
- Traffic count on some main roads and corridors.

4.3. Data preparation

4.3.1. Road network preparation

In this research, one important task is the preparation of the road network. The road network is prepared from a paper map since the research scholar could not get the road network of Hanoi in GIS format. The whole process of road network preparation is depicted in the flowchart below.

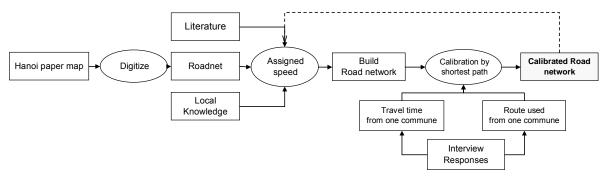

Figure 4.8: Process of road network preparation

Digitization process and the road network building is followed the instructions in Network Analysis & Linear Referencing tools (Bosch 2006).

The road net is digitized in quite detail with seven road classes: highway, main road, secondary road, minor road, link road, lane and internal road. A road is divided into segments, from junction to junction. The road class is decided based on the local knowledge of research scholar and the Report on Current Condition of Road Network from Public Work Service in 2006.

Basically, the speed for each road segment is decided based on its road-class and its length with a suggestion of road speed from table 4-7, chapter IV, Urban Road Design by Nguyen Khai in 1999(Nguyen Khai 1999) as in the table below.

| Distance between two intersections (m) | Maximum speed Vmax(km/h) | Average speed of traffic flow Vavg (km/h) |
|---|-----------------------------|---|
| 200 | 35-40 | 14-16 |
| 400 | 45-50 | 18-20 |
| 600 | 65-70 | 26-28 |
| 800 | 80-85 | 32-40 |
| 1000 | 95-100 | 38-40 |

| Average | Speed of | Traffic | Flow | (table | 4-7, | (88qq |
|---------|----------|---------|------|--------|------|-------|
| | | | | (| , | |

Table 4.5: Average speed of traffic flow (Source: Table 4-7, Urban Road Design-Nguyen Khai)

4.3.2. Calibration of road network

From the suggestion in the table 4.5, the travel cost (or impedance) is calculated for each road segment for the way "From-To" and the reverse direction "To-From" (From-To is the direction of digitizing) by assigning travel speed. The assigning process is based on the road type and its length.

Finally, the whole road network is built and then calibrated based on the information extracted from interview responses. There are two important task need to be checked are the travel route and travel time from a ward to specified destination.

Route checking: Since the analysis in the next chapters is based on the shortest path algorism calculated from prepared road network in the previous steps. The shortest path from a ward to a specified destination is calculated based on the least accumulated cost of all possible road segments. The travel cost is depended on the length of the road segment and the assigned travel speed as mentioned in the previous step. If the travel speed assigned for one road segment is not correct, our road network model might give the wrong corridors for travel from a ward to a destination in our study area as compared with the real situation information which extracted from the interview and local knowledge of the research scholar. Therefore, it is necessary to calibrate the road network before using in the next chapters by checking the route used given by model and the corridors used from the same ward extracted from the interview. This process is called road network calibration.

The strategy applied is to divide the whole city into some bigger areas (bigger than commune) for example: Gia Lam area (from the other side of the river), Dong Anh area (from the North of the city), Thanh Xuan-Ha Dong area (from the South-West direction), Cau Giay-Dich Vong-Dien-Nhon area (from the West, etc. People from these areas must use some specific corridors. There is almost no other choice for them. For example, there is only one choice for people from the other side of the river to Bach Mai area: Chuong Duong bridge-Ba Trieu-Dai Co Viet; people from Cau Giay-Dich Vong-Nhon to Viet-Duc, K,C hospitals must use Cau Giay bridge-Kim Ma-Nguyen Thai Hoc; people from Thanh Xuan-Ha Dong must use Nguyen Trai-Nguyen Luong Bang-Kham Thien to urban core, etc. This strategy is based on the local knowledge of research scholar.

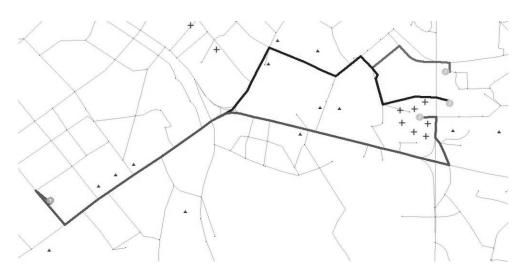

Figure 4.9: Route used from a ward to destination in the study area.

Travel time checking: The task is completed by comparing the travel time given by model and the information extracted from the interview.

After many times of adjustment, the travel speed of the road network is assigned with the value in the table 4.6 below.

| _ | | | | | | |

Speed table Traffic Flow

Note: Number in bracket is applied for Oneway road

Table 4.6: Speed table of road network

After calibration the road network is valid and ready for analyse in the next step.

4.3.3. Calculate road capacity in normal condition

The following part is summarizing from chapter IV, Urban Road Design by Nguyen Khai, published by Transport Publisher in 1999(Nguyen Khai 1999).

4.3.3.1. Definition of road capacity:

Road capacity in normal condition is the maximum number of vehicle that can run through a road section in a certain unit of time. It is also considered as road capacity at a certain expected speed of traffic flow running on the road. If the actual traffic volume on the road is over the road capacity, the running speed of the vehicle will be lower than the expected speed. The unit usually used is passenger car unit per hour (pcu/h).

Therefore, by comparison between road capacity and the actual volume of vehicle running on road we can evaluate congestion level of the roads.

Road capacity of a road depends on the number of lane, average speed, travel length between two cross sections and type of intersection.

4.3.3.2. Capacity of one lane:

In perfect condition, the capacity of one lane is calculated as follows:

N=
$$\frac{1000V}{\frac{V}{3.6} * t + \frac{V^2 K}{254(\phi+i)} + L + Lo}$$
 (1)

With:

| N: Road capacity (pcu/h/lane) | i: Longitudinal inclination of the road. |
|--|--|
| V: Average speed (Km/h) | t: Safety time for action of driver. (t=1-1.2 |
| L: Car's length (L=5m for passenger car) | seconds) |
| Lo: Safety distance between 2 cars. (Lo=3- | $\boldsymbol{\phi}:$ Friction coefficient between car tire and |
| 5m.) | road surface (ϕ =0.2-1, depends on the |
| | condition of road surface). |

4.3.3.3. Some factors affect to road capacity

a. Influence of number of lane to road capacity:

The capacity of each lane is not the same, even in the same running direction. The lane near the centre line of the road has higher capacity than outside lanes. According to observation, the capacity of lanes is as follows:

| Lane position (count from road center line) | Capacity coefficient (γn) |
|---|------------------------------|
| 1 | 1 |
| 2 | 0.85 |
| 3 | 0.7 |
| 4 | 0.5 |
| 5 | 0.4 |

| Number of lane in the same running direction | Average capacity coefficient (γ) |
|--|----------------------------------|
| 1 | 1 |
| 2 | 0.92 |
| 3 | 0.85 |
| 4 | 0.76 |
| 5 | 0.69 |

Table 4.7: Lane coefficient

The capacity of lane n will be calculated as follows: Nn=N1* γn

N1: Capacity of lane number 1.

γn: Capacity coefficient of the lane n.

Therefore, the capacity of the road depend on the number of the lane in the same direction

b. Influence of intersections at the same level

Intersection at the same level has great influence to the capacity of the road, especially at intersection with traffic lights. The average speed of vehicle is reduced depending on the distance between two intersections. As observation, the average speed of traffic flow is recommended in the table below:

| Distance between two intersections (m) | Maximum speed Vmax(km/h) | Average speed of traffic flow Vavg (km/h) |
|---|-----------------------------|---|
| 200 | 35-40 | 14-16 |
| 400 | 45-50 | 18-20 |
| 600 | 65-70 | 26-28 |
| 800 | 80-85 | 32-40 |
| 1000 | 95-100 | 38-40 |

Table 4.8: Average speed of traffic flow

This suggestion is also fit with the survey by research scholar during fieldwork. For example, Truong Chinh Street has average distance between interruption is 200m and the survey speed is around 16km/h (4.65 m/s * 3,600 s=16.74km/h) as depicted in the figure 4.9.

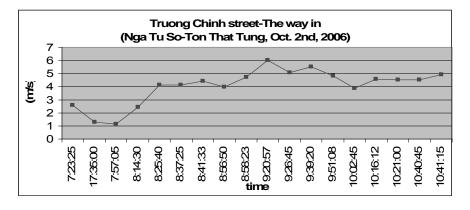

Figure 4.10: Travel speed on corridors

Due to the same level intersection, vehicle must stop at intersection waiting and the travel time between two section increases. Therefore, road capacity is reduced with coefficient α .

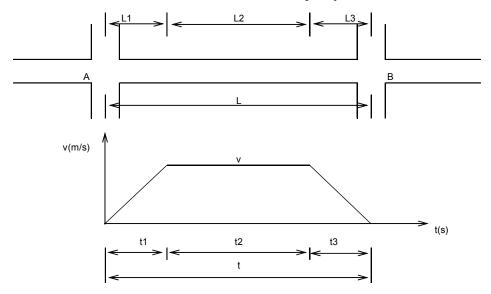

Figure 4.11: Chart for calculation of coefficient α

Coefficient α is calculated as follows:

$$\alpha = \frac{tAB}{t1+t2+t3+\Delta} = \frac{\frac{1}{v}}{\frac{v}{a} + \frac{12}{v} + \frac{v}{b} + \Delta}$$
(2)

In which:

v: average speed (m/s)

l: Distance between two intersections (m)

a: Average acceleration of vehicle when starting (m/s2) (a=0.60-0.67m/s2 for passenger car)

b: Average acceleration of vehicle when stopping (m/s2)(b=1.66 m/s2for passenger car)

 Δ : Average stopping time for street light (s) (Δ =15-20s)

From this formula, we can see that if the $\alpha 1$ smaller if the distance between two intersections small and the speed high.

c. Influence of the lane width (K1).

If the lane width (b) is smaller than 3.5 the average speed will be reduced. Therefore, the road capacity will be reduced also. The factor K1 is determined as recommended in the table below:

| Lane width (m) | K 1 |
|----------------|------|
| 3.50 | 1.00 |
| 3.25 | 0.94 |
| 3.00 | 0.85 |
| 2.75 | 0.77 |

Table 4.9: Coefficient of lane width

d. Influence of pedestrian across the road (K2)

K2=0.63 if the number of pedestrian is over 500 persons/h, otherwise K2=1. This coefficient K2 is not applied in this research.

e. Other factors (K3)

There are some more factors that can have influence to road capacity like railway crossing, mode share and driver behaviour, etc. This factor should be collected on the field. The coefficient K3 is not applied in this research.

4.3.3.4. Road capacity

From theory discussed above, we can calculate the capacity for one running direction of a road as follows:

$$No = N * (\alpha * \gamma * K1 * K2 * K3)$$
(3)

Or

$$N_{0} = N^{*}(\gamma^{*}\alpha^{*}K1^{*}K2^{*}K3) = \frac{1000V}{V}^{*}(\gamma^{*}\alpha^{*}K1^{*}K2^{*}K3)$$
(4)
$$\frac{V}{3.6} \times V^{2}K + L + Lo$$

According to Road Design Specification 20TCN-104-83, the road capacity of one lane can be referred in the table below:

| Converted vehicle | | ed intersection cu) | Intersection with the | | |
|-------------------|-----------|------------------------|-----------------------|--|--|
| | Highway | Main road | same level (pcu) | | |
| Passenger car | 1200-1500 | 1000-1200 | 600-700 | | |
| Truck | 600-800 | 500-600 | 300-400 | | |
| Bus | 200-300 | 150-250 | 100-150 | | |
| Tram | | 110-130 | 70-90 | | |

Average capacity of one lane (pcu)

Table 4.10: Suggestion of road capacity of one lane

In Hanoi case, most of roads intersect with each other at the same level therefore the average capacity of one lane is about 600-700 pcu/h.

In this research, all main corridors and congested roads are selected for capacity calculation. The result is listed in the table below:

| No. | Road name | Corridor code | Road width(m) | Oneway | Road type | Number of lane | Average length (m) | Average speed (km/h) | Average speed (m/s) | Lane width (m) | K1 | α | Σγn | γ | Road capacity (pcu/h) |

Capacity of some main roads and corridors

Note:

- For road capacity calculationy, all transport modes are converted into tourist car (PCU).

- Average speed is refered from table 4-7 (Urban Road Design -Nguyen Khai, 1999)

- If road type is Secondary and the road is oneway road, the low speed value of one upper level will be applied

- If road type is Main road, the upper value of one upper level is applied.

Table 4.11: Road Capacity of some corridors

The calculated road capacity will be used for evaluating congestion level by comparing with the current traffic volume and traffic volume in scenarios in the next chapters.

5. Contribution of some selected major land uses to congestion

5.1. Selected corridors

5.1.1. Corridor selection

To evaluate the contribution of some major land-uses to traffic congestion, the main corridors leading to these locations and congested roads have been selected and then divided into 36 segments. Based on traffic counts on selected corridors as provided by ALMEC Corporation and based on local knowledge of the research scholar, these segments have been divided into 2 groups: Group 1 are road segments which suffer severe congestion in current situation or are main corridors leading to the city centre. They are listed in the table 5.1 below.

| No. | Road name | Corridor code | No. | Road name | Corridor code |

Corridor group 2

Table 5.2: List of corridor group 2

(*) The different scenarios will be introduced in chapter 6.

Corridor group 1 are segments depicted in red colour, while corridor group 2 segments are in blue colour in figure 5.1 below.

5.1.2. Peak hours

Traffic counts as done by ALMEC in February, 2005 reveal that the morning peak hour is generally from 7:00AM to 8:00AM and the afternoon peak hour is from 17:00PM to 18:00PM. In Appendix B, the counts are listed.

5.1.3. Calculate traffic volume on road segments in peak hours

The ALMEC study only provides traffic counts for some selected locations. Therefore, based on these counts, estimates have been made for traffic on the other segments, for this research considered important. This is done by applying a so-called Q-factor separately for each corridor group. Based on the traffic count by ALMEC, the Q-factor is calculated as follows:

```
Q-factor = ALMEC traffic count/Road capacity. (5)
```

After that we will calculate the means (μ) of the Q-factors separately for each corridor group and separately for morning peak as well as for afternoon peak. The means (μ) of the Q-factors is used to determine the traffic volume for all remaining **corridors**, which do not have a traffic count. The calculation is also done separately for morning and afternoon peaks, and for the way in and the way out of city centre.

The results of the calculation are shown in the table below:

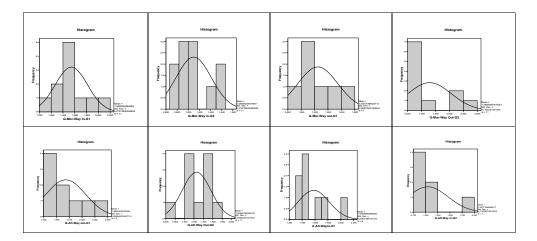

Figure 5.3: Histogram of Q-means

| Г | | | | | | Morning | -Way in | | Morning-Way out | | | |

| Peak | Volume | calculation-Afternoon |
|------|--------|-----------------------|
|------|--------|-----------------------|

Table 5.4: Calculation of current traffic volume on corridors-Afternoon peak

5.2. Congestion level

In order to evaluate the congestion in current situation and scenarios congestion levels are applied. Congestion level is proposed to measure by ratio of actual traffic volume and road capacity:

For calculation of road capacity, please refer to paragraph 4.3.4.

Nine grades of congestion are proposed for evaluation of congestion in the current situation and scenarios, which will be constructed later.

Figure 5.4: Congestion level

From the traffic counts by ALMEC, the maximum of traffic volume and road capacity ratio is 2.587 on the way out at Chua Boc Street in the afternoon. The grade is proposed based on the local knowledge of the research scholar, for example in Chua Boc, Thai Ha streets in the afternoon it hardly moves because the roads are almost full of vehicles, while in the morning it is somehow better and by comparison it is between some of the most severe congested roads and other roads in Hanoi.

Based on this definition, the congestion level of the current situation is calculated as in the table below. The calculation is separated for the way in, the way out of the city centre; and separated for the morning and afternoon peaks as well as for corridor groups 1 and 2.

| | | | | | | Morn | ina | Afternoon | | | | |

| 36 | Dai Co Viet (Lduan-Batrieu) | No. 26-D.C.Viet | 2 | 2,793 | 3,067 | Crowded | 3,592 | Very crowded | 2,927 | Crowded | 3,504 | Very crowded |

Congestion level of corridors-Current situation

Note: Nguyen Thai Hoc street, Ba Trieu street and Pho Hue street are one way streets.

In reality, Truong Chinh Street is as congested as Chua Boc Street, especially on the way-out in the afternoon, but we do not have traffic count at this corridor. Anyway, this calculated result can be acceptable and in future this calculation should be updated with new traffic count if we have.

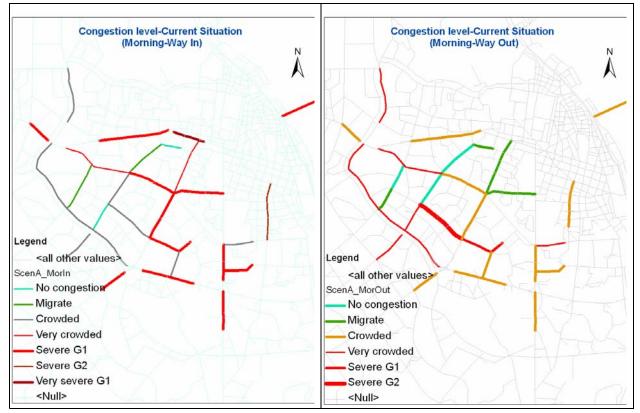

The result is summarized in the table 5.6 below. The number of segments and their congestion level for the different situations is indicated.

| | Morning Way In | Morning - Way Out | | Afternoon- Way Out |
|----------------|-------------------|----------------------|----|-----------------------|
| No congestion | 2 | 3 | 2 | 1 |
| Migrate | 3 | 5 | 2 | 0 |
| Crowded | 10 | 14 | 10 | 4 |
| Very crowded | 3 | 9 | 6 | 13 |
| Severe G1 | 15 | 2 | 12 | 11 |
| Severe G2 | 1 | 1 | 2 | 1 |
| Very severe G1 | 1 | 0 | 1 | 0 |
| Very severe G2 | 0 | 0 | 0 | 3 |
| Craw | 0 | 0 | 0 | 1 |

Table 5.6: Summarize result of congestion level-Current situation

From this summary table 5.6, we can see clearly that the way-out in the afternoon is the most severely congested and in the morning the way-in is more severe than the way out.

The current situation is developed as shown below in figure 5.7. The different segments are coloured according to their congestion level.

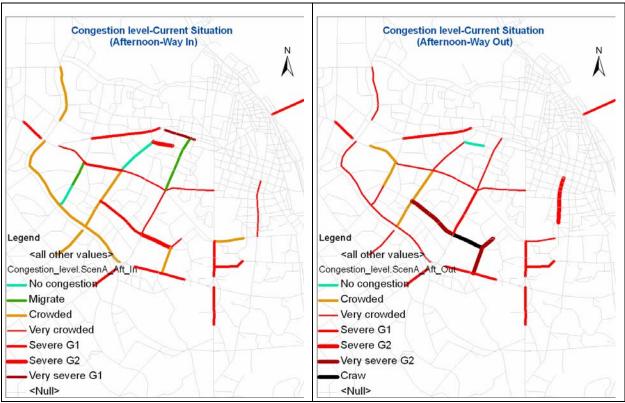

Figure 5.5: Congestion level-Current situation

5.3. Congestion mark

In our scenarios, the congestion situation might be reduced in one direction but might be increased in the reverse direction or it reduces on some corridors but increase on another corridors. How can we evaluate and know which scenario is better than the other?

This matter can be solved by introducing a marking system and introduce a weight for each congestion level as defined above. The idea is based on EIA (Environmental Impact Assessment) and MCE (Multi Criteria Evaluation) methods.

The marks and weights are usually given with the consensus between experts depend on the importance of the criteria. In this research, these values are given with the consensus between the research scholar and his advisors.

| No. | Congestion level | Mark | weight |
|-----|------------------|------|--------|
| 1 | No congestion | 10 | 1 |
| 2 | Migrate | 8 | 1 |
| 3 | Crowded | 2 | 1 |
| 4 | Very crowded | -2 | 1 |
| 5 | Severe grade 1 | -3 | 2 |
| 6 | Severe grade 2 | -4 | 2 |
| 7 | Very severe G1 | -6 | 3 |
| 8 | Very severe G2 | -8 | 3 |
| 9 | Craw | -10 | 3 |

The mark is given from -10 to +10. A weight is given from 1 to 3: (+)10 is given to "No congestion", (-)10 is given to "Craw". Weight is given with a notion that if one scenario produces one more severe grade 2 it should also produce one migrate or 4 crowded segments for compensation or in other words it is not preferred to see severe, very severe and caw cases.

Based on this idea, congestion mark of the current situation is calculated in the table below. A good congestion mark for a scenario is positive, otherwise negative.

| Regime | Congestion level | Mark | Weight | Morning Way In | Morning - Way Out | Afternoon- Way In | Afternoon- Way Out | Sum | Total Mark |
|----------------|------------------|------|--------|-------------------|----------------------|----------------------|-----------------------|-----|------------|
| | No congestion | 10 | 1 | 2 | 3 | 2 | 1 | 8 | 80 |
| Flow Regime | Migrate | 8 | 1 | 3 | 5 | 2 | 0 | 10 | 80 |
| | Crowded | 2 | 1 | 10 | 14 | 10 | 4 | 38 | 76 |
| | Very crowded | -2 | 1 | 3 | 9 | 6 | 13 | 31 | -62 |
| | Severe G1 | -3 | 2 | 15 | 2 | 12 | 11 | 40 | -240 |
| No Flow | Severe G2 | -4 | 2 | 1 | 1 | 2 | 1 | 5 | -40 |
| Regime | Very severe G1 | -6 | 3 | 1 | 0 | 1 | 0 | 2 | -36 |
| | Very severe G2 | -8 | 3 | 0 | 0 | 0 | 3 | 3 | -72 |
| | Craw | -10 | 3 | 0 | 0 | 0 | 1 | 1 | -30 |
| | | | | Sum | | | | | -244 |

Congestion Mark-Current situation

Table 5.8: Congestion mark-Current situation

In the current situation, the total congestion mark is -244. This situation will be compared with the congestion situation in the scenarios, which will be developed in the chapter 6.

5.4. Characteristics of the selected major land uses

5.4.1. General information

This section will give you a general idea about the locations that will be moved in the scenarios. Study area 1 is where 3 universities and 7 hospitals are located while study area 2 is in the urban core.

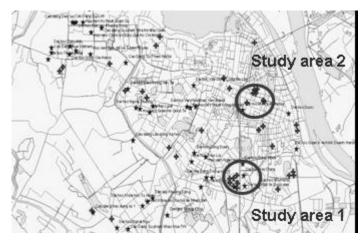

Figure 5.6: Study areas

5.4.2. Study area No. 1

Study area No. 1 includes 3 universities and 7 hospitals within Bach Mai hospital boundary.

Three universities:

Three universities are Polytechnics University, Construction University and Economics University (PCE Uni.). These universities were founded about 50 years ago. The total numbers of student study at base camp are almost 70,000 students among them Hanoi students are just account for 23.7%, the rest are coming from other provinces (called outside students).

| No. | University name | No. of staff | Total number of students | No. of students study at Hanoi base | Reference | | | | | |
|-----|-------------------------|----------------------------------|--------------------------|---|--|--|--|--|--|--|
| 1 | Construction University | 832 | 23,060 | 23,060 | Construction University's Bulletin No. 32, September, 2006 | | | | | |
| 2 | Economics University | 1,950 | 30,000 | 30 000 | Economics University-50 years of Construction and Development,2006. | | | | | |
| 3 | Polytechnics University | technics University 1,130 27,996 | | 18,700 | Polytechnics University-50 years Keynote, 2006. | | | | | |

(Bulletin 2006; Eco_Keynote 2006; Keynote 2006)

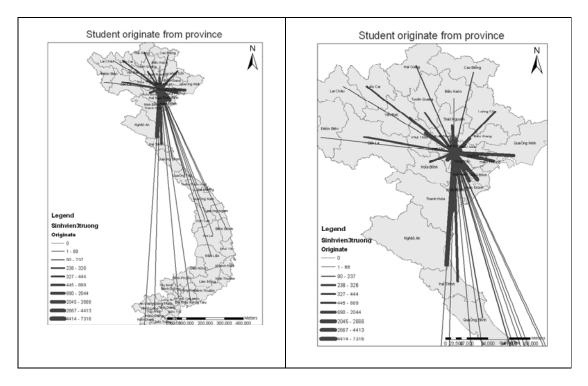

Figure 5.7: Origin of students.

The universities are the main destination not only for bachelor students but also for Msc., PhD. students as well as Second Degree and In-service students. Bachelor students account for about 50% of total students(Bulletin 2006; Eco_Keynote 2006; Keynote 2006).

| No. | University name | Bachelor | Other courses | Total | Reference |
|-----|-------------------------|----------|---------------|--------|--|
| 1 | Construction University | 13,200 | 9,860 | 23,060 | Construction University's Bulletin No. 32, September, 2006. |
| 2 | Economics University | 13,732 | 12,281 | 26,013 | Economics University-50 years of Construction and Development,2006. |
| 3 | Polytechnics University | 15,800 | 14,280 | 30,080 | Polytechnics University-50 years Keynote, 2006. |

Table 5.10: Bachelor students compared with total students

One more important characteristic of these universities is that they have 3-shifts classes: Morning class, Afternoon class and Night class. Morning class starts very early in the morning, usually at 6:45AM. Therefore, only few students commute during morning peak hour. But in the afternoon, the afternoon classes finish around 17:00 to 17:15 PM and Night classes start at 18:00 PM. Therefore, in the afternoon peak hour universities attract and release quite a lot trips. Traffic count at cordons and questionnaire responses performed in this study reveal that only 5.5% of students commute during morning peak hour. It also means that 97.2% of students contribute to congestion.

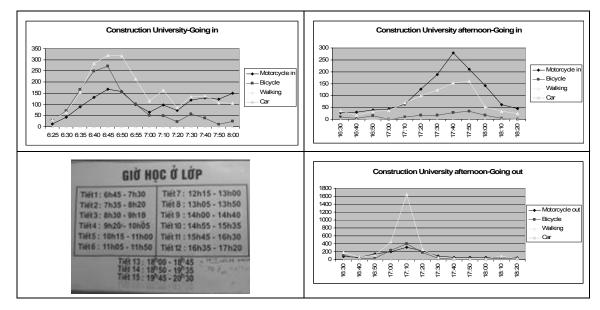

Figure 5.8: Traffic count at cordon of Construction University

Mode share: 39.4% of students commuting by bicycle or walk, 20.1% use Hanoi bus and only 37.5% uses a motorcycle.

In the future, these universities will develop and expand; the number of student will increase also. For example Polytechnics University is expected to increase the number of students up to 37,000 students by 2010, while the existing facilities are already overloaded. Therefore, in 2001 the minister of education proposed to build new university village with total area of 350 ha at Tay Mo commune for expansion as mentioned in the document 2236/KHTC dated March 23rd, 2001 to the prime minister which was approved by issuance 564/CP-KG dated June 22nd, 2001. The new locations are in Tay Mo village on the West direction as shown in the figure below(MOE 2005).

Figure 5.9: Location of university village

However, details of the expansion are not clearly mentioned in the document, as well as project report; for example there is no information on which department will be moved out, which student group will study at the new base, etc.

Bach Mai hospital and other hospitals within Bach Mai boundary:

Bach Mai hospital was founded in 1911. Bach Mai is one of the biggest hospitals at national level. It means that Bach Mai is the last destination for patient after the treatment at provincial level failed. Bach Mai is well-known with good quality and services. Recently, some departments have dispatched from Bach Mai hospital like National Institute of Hematology and Blood Transfusion, National Institute of Infection and Tropical Diseases and 4 other Institutes as depicted in the figure above. The Interview of Management Board reveals that most of them have the intention to relocate but they do not have clear idea where to go till now. 'It is far future'' as they said, except National Institute of Hematology and Blood Transfusion already have land for a new base at Nhan Hoa-Trung Kinh-Hanoi. All of them are temporarily located within the same boundary at this moment.

| | Hospital name | | | Staff | | P | atient | | | | | |
|-----|--|-----------------------|-----------------|-----------------------------|-------|------------------------------------|-----------------------------|-------|------------|---------------------------|-----------------------|-----------------------|
| No. | | No. of patient bed | Number of staff | No. of completed form | % | Average number of patient daily | No. of completed form | % | Relocation | New address | Type of relocation | Year of relocation |
| 1 | Bach Mai hospital consortium | 1700 | 2875 | 684 | 23.79 | 2651 | 637 | 24.03 | | | | |
| а | Bach Mai Hospital | 1150 | 1925 | | | 1516 (33362/22 days) | | | Not yet | Waiting for permission | | |
| b | National Institute of Infectuous and Tropical Diseases (Vien Lay) | 120 | 200 | | | 80 | | | Yes | Not clear now | | |
| | National Institute of Hematology and Blood Transfusion (Vien Huyet hoc) | 200 | 300 | | | 35 | | | Yes | Nhan Hoa-Trung Kinh-Hanoi | Move all | 2010 |
| d | National Institute of Dermato- Venereology (Vien Da lieu) | 100 | 200 | | | 400-700 | | | Yes | Not clear now | | |
| е | Vietnam National Institute of Gerontology (Vien Lao khoa) | 30 | 50 | | | 20 | | | Yes | Not clear now | | |
| f | Vietnam-French Hospital | 100 | 200 | | | 300 | | | No | | | |

Table 5.11: General information of hospitals within Bach Mai hospitral boundary

All locations are suffering from overcrowding and overloading situation. One can see that hospitals are always full of people. Cordons traffic counts conducted in this area and pictures

below can give you some idea of how busy they are. Many people go in the hospitals during peak hour and up to 9:00AM almost 9,000 people going in hospitals in total.

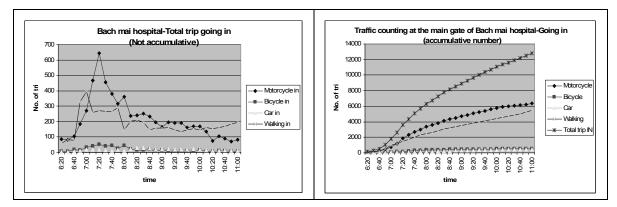

Figure 5.10: Traffic count at Bach Mai cordons

Figure 5.11: How busy they are-In Bach Mai hospital

Interview results show that Hanoi patients just account for only 33.6%, the rest are coming from almost half of the country, especially provinces around Hanoi like Vinh Phuc, Ha Tay, Ha Nam, Nam Dinh, Thai Binh provinces, etc. Only 51.3% of them use motorcycle, 28.6% going by intercity bus, 8.2% going by Hanoi bus, only 11.2% going by green modes.

Questionnaire responses also revealed that 87.3% (440 peak cases/504 responses) of Bach Mai staff commute during morning peak hour and 84.12% (482 peak cases/573 responses) in the afternoon peak. And among them 83% use motorcycle in the morning and 85% in the afternoon peak hour. Total number of people use green modes is less than 15%.

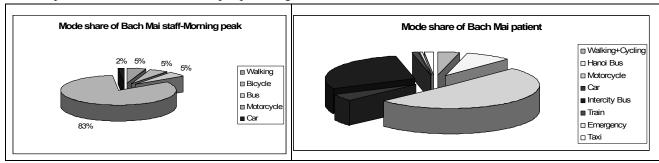

Figure 5.12: Mode share of Bach Mai staff and patient

Like teaching staff and students for the university locations, travel time by bus is almost double travel time by motorcycle and travel time back home in the afternoon is about 10 minutes longer than in the morning. It explains why people prefer motorcycle than bus and it also gives us an idea that congestion in the afternoon is more severe than in the morning.

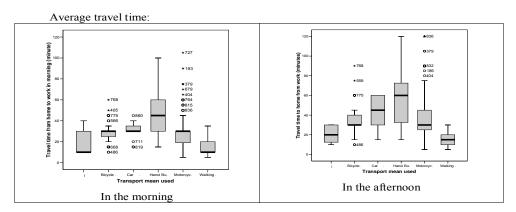

Figure 5.13: Travel time of Bach Mai hospital staff

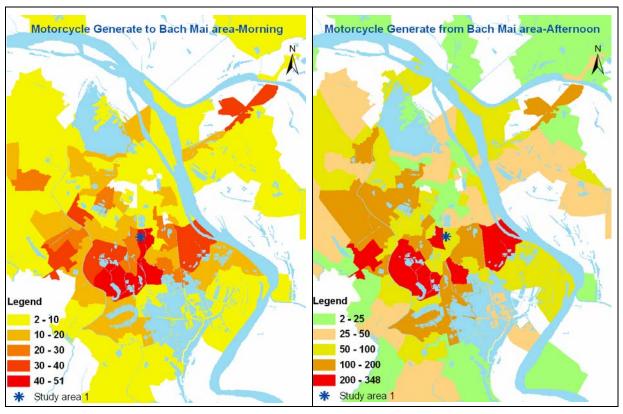

Figure 5.14: Motorcycle generation and return from study area No.1

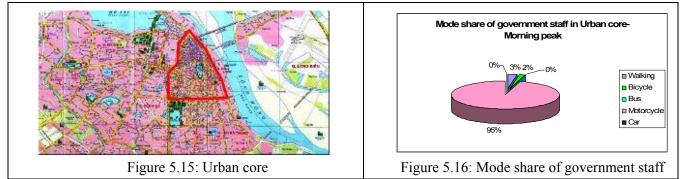

The figures above indicate origin locations densities of staffs, patients and students, and thus give us an idea where people live. Most of them live in the South and the West of our study area.

5.4.3. Study area No. 2

Study area No. is in the Hoan Kiem district or urban core. Nowadays, urban core become a business centre and tourist centre.

Government offices:

According to the survey of economics enterprises, administration enterprises within Hanoi area by General Department of Statistics in July, 2002, Hoan Kiem district has 16,218 staffs working in administration offices at national level and 22,030 people working in business enterprises; Ba Dinh district has 93,331 staffs and 9840 people respectively(Statistics 2003). That is why Ba Dinh district is considered as administration district and Hoan Kiem district is considered as business centre.

Interview result reveals that 95% of government staff uses motorcycle and 95.5% of them commute during morning peak hour and 79.85% commute during afternoon peak hour. The number of staff that uses green modes is less than 5%.

Viet-Duc, K and C hospitals

Similar with Bach Mai hospital, these three hospitals are hospitals at national level and are the last destination for patient after the treatment at provincial level failed. Hanoi patients just account for 32.9% and 52.6% of them use motorcycle going to the hospital, 22.7% going by intercity bus and 10.2% uses green modes. Many of them lost 3-5 hours on average to go to hospitals.

According to the interview result, 72.33% of the hospital staff use motorcycle and 77.24% of them commute during morning peak hour and 74.44% commute during afternoon peak hour.

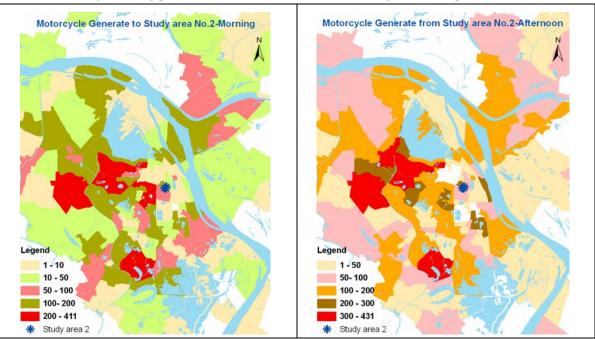

Figure 5.17: Motorcycle generate and return from urban core.

The figures show that most of people are living in the South and in the West of our study area.

5.5. Contribution to congestion of the selected land uses.

5.5.1. Methodology

To answer the research question "How much these land uses contribute to traffic congestion on the selected corridors?" we need to know how many pcu (passenger car unit) per ward are generated (in the morning) and attracted (in the afternoon); and which routes one use TO and RETURN from one commune to destinations in our study areas. The general methodology flowchart is as follows:

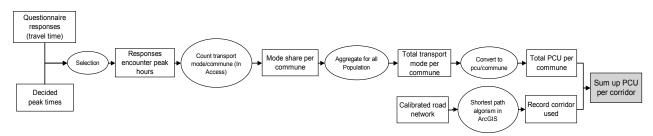

Figure 5.18: Congestion contribution flowchart

Firstly, we must select all records of people who commute during peak hours from the questionnaire responses. The selection is separately for morning peak and afternoon peak. The work is completed easily in spreadsheet.

The result is summarized in table 5.12 below:

| No. | Organization name | Total Population | Morning peak encounter/Responses | Percentage (%) | Afternoon peak encounter/Responses | Percentage (%) |
|-----|---------------------------|------------------|-------------------------------------|-------------------|---------------------------------------|-------------------|
| 1 | Study area No. 1 | | | | | |
| 1 | Bach Mai staff | 2875 | 440/504 | 87.3 | 482/573 | 84.12 |
| 2 | Bach Mai patient | 2651 | 234/531 | 44.07 | | |
| 3 | Polytechnics staff | 1950 | 53/76 | 69.74 | 24/36 | 66.67 |
| 4 | Polytechnics students | 30,000 | 7/158 | 4.43 | 340/369 | 92.14 |
| 5 | Construction staff | 832 | 31/122 | 25.41 | 31/38 | 81.58 |
| 6 | Construction student | 23,000 | 25/537 | 4.66 | 613/619 | 99.03 |
| 7 | Economics staff | 1130 | 31/48 | 64.58 | 29/48 | 60.42 |
| 8 | Economics student | 18,700 | | | 436/577 | 75.56 |
| Ш | Study area No. 2 | | | | | |
| 1 | Government Office staff | 16,218 | 128/134 | 95.52 | 191/196 | 97.45 |
| 2 | Viet-Duc hospital staff | 982 | 209/255 | 81.96 | 172/245 | 70.21 |
| 3 | Viet-Duc hospital patient | 400 | 57/137 | 41.61 | | |
| 4 | K hospital staff | 557 | 186/217 | 85.71 | 174/217 | 80.18 |
| 5 | K hospital patient | 800 | 98/152 | 64.47 | | |
| 6 | C hospital staff | 600 | 173/207 | 83.58 | 152/207 | 73.43 |
| 7 | C hospital patient | 250 | 53/108 | 49.07 | | |

Table 5.12: Number of people commutes during peak hours

From the selected records as mentioned above, we need to know how many cars; motorcycles and bicycles are generated or attracted from one ward. This task is completed by applying grouping queries in the questionnaire database.

The number of all transport mean is recorded for each commune and sum up in table 5.13. After that these numbers are aggregated from the sample to the whole population with the assumption that the whole population have the same characteristics as the sampling population.

There is one note here is that universities have 3 shift classes as noted before, and that we assume that facilities (class rooms) are utilized fully. Therefore, one third of the student population will go to class in the morning, one third will go in the afternoon and remaining one third will attend night classes.

And then the aggregated number of car and motorcycles are converted into passenger car unit (PCU).

$$PCU = Number of car *1.0 + number of motorcycle*0.3$$
(8)

In this calculation, only car and motorcycle are taken into account; walking, cycling and buses are considered as "green modes" and do not contribute to congestion. A short table below is an example.

| | | | Bac | ch Mai ho | ospital s | taff (Afte | rnoon pe | eak) | | | |
|--------------|----------|----------|---------|----------------|-----------|------------|------------|----------------------|----------------|-------------|-----|
| From commune | No. of r | espone a | mong 48 | 2 cases (| 482/573) | Summari | ze for who | e Bach Ma staffs) | ii hospital s | staff (2875 | PCU |
| | Walking | Bicycle | Bus | Motorcycl e | Car | Walking | Bicycle | Bus | Motorcycl e | Car | |
| Bach Dang | | | | 2 | | | | | 10 | | 3 |
| Bach Khoa | 1 | 1 | | 2 | | 5 | 5 | | 10 | | 3 |
| Bach Mai | | | | 2 | | | | | 10 | | 3 |
| Bat Trang | | | | 1 | | | | | 5 | | 2 |

Table 5.13: Example of pcu calculation

The remaining task is to record the routes one used from one commune to the destination and return. This task is completed by applying a Shortest Path Algorithm in ArcGIS with some assumptions as follows:

- People go and return from a ward's centre directly.
- People use the route which has least cost trip measured in time unit (seconds).

This task is done separately for each organization since people might use different ways to go to organizations in the same study area even they start from the same origin point as depicted in the figure below.

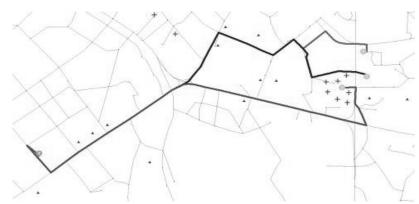

Figure 5.19: Different routes used to organizations in the same study area

Accordingly the corridors that are used are recorded in a route count table as depicted in table 5.14 below. This work is done by hand since the research scholar has not found a better way in ArcMap. It is time consuming work and could be done faster if it was programmed. As students in afternoon classes will return home and students in the night classes will come to universities for study, both the way in and the way out should be taken into consideration for universities in the afternoon.

| | | Travel length bach home | Corridor used to Bach Mai hospital (shortest path) | | | | | | | | | | | | |
|-----|--------------|----------------------------|--|-----------------------|------------------|------------------|------------------|--|--|--------------|---|---|-------------------|--|--|

| Table 5.14: Example | of corridor count table |
|----------------------|-------------------------|
| Tuble 5.1 T. Example | |

Next, total numbers of trip running on the selected corridors is calculated by multiplying aggregated PCUs with the corridor count and then sum up in a table for each study area separately the way in and the way out. The following tables are an example.

| | | | Corrid | or used to | Dooh M | i oroo | | | | | |
|----|-----------------|--|--------|------------|--------------------------------|--------|-----|--------|-------------------|---------|------------------|

Table 5.16: Example of sum up total trip table to study area no.1 – Morning-way in

Finally, a summarize table is made for both study area no.1 and no.2 to calculate the contribution of our study areas to congestion by comparing with current traffic volume calculated before (For detailed, please see Appendix C)

5.5.2. Contribution to congestion of the selected land uses

The summarize table below has shown that the selected land uses have considerable contribution to congestion on the selected corridors for example: at Chua Boc and Pham Ngoc Thach streets in the morning, study area no.1 contributes just about 23% and 32% respectively on the way in but in the afternoon they contribute 55% and 81% in the same direction and contributes 43% and 56% on the way out; at Kham Thien street in the morning, study area no.2 contribute 69% on the way-in and 73% in the afternoon in the reverse direction and in total both study areas contribute 73% in the morning and 93% in the afternoon.

| | | | | | Mor | ning | | | | | After | noon | | |

Note: The number in the table is the percentage compared with the current traffic volume on the selected corridors

Table 5.17: Contribution to congestion of the selected land uses.

5.6. Conclusions

To figure out the contribution to congestion, 36 road segments of all main corridors and congested roads are selected to evaluate the contribution of people from two study areas. The study area no. 1 is Bach Mai area where 3 big universities with almost 70,000 students and a group of 7 hospitals are located. The research reveals that this area attracts quite a lot of trips in the morning and even releases more trips in the afternoon to some corridors near-by, since 97.2% of students use these corridors during the afternoon peak hour. For example, in the morning on the way-in of Chua Boc, Pham Ngoc Thach, and Thai Ha streets with considerable contribution of 23%, 27% and 23% respectively, but in the afternoon they contribute to both the way-in and the way-out: 54.7%, 81.3% and 43.9% respectively in the way-in and 43.7%, 56.5% and 27.6% respectively in the way-out; The study area no.2 is in the urban core where 161 government offices with 16218 staffs at national level and 3 hospitals are located. The survey reveals that 95% of government staffs use motorcycle and 95.5% of them commute during peak hours. That is why some main corridors like Kham Thien, Nguyen Thai Hoc, and Kim Ma streets are always under high congestion pressure. The contribution of study area no. 2 to these corridors are 68.7%, 42.5% and 26.2% respectively on the way-in in the morning and 72.8%, 0% and 37.8% on the way-out in the afternoon (Nguyen Thai Hoc is one way road).

Nine grades of congestion and congestion mark have been proposed to evaluate the current situation of congestion. In chapter 6, it is studied how much can we improve by relocating these land uses in our scenarios developed.

6. Scenarios for relocating some major land uses

This chapter discuss on some scenarios of relocation and their effect on congestion in Hanoi's city centre. The scenarios are designed as such to study different combinations of levels of relocation as compared to levels of road capacity. All scenarios are related to the current situation levels of relocation vary from the one extreme of removing all activities, no relocation, to particle (50%) and full relocation (100%). The transport road capacity varies from the existing road segments to a situation where selected segments are expanded (in line with current ideas in Hanoi).

| | No Relocate | Relocate all to the West | Relocate 50% |
|----------------|-------------------|--------------------------|--------------|
| No Activity | Scenario O | | |
| Existing road | Current Situation | Scenario 2 | Scenario 3 |
| Road Expansion | Scenario 1 | Scenario 4 | Scenario 5 |

Six basic scenarios are proposed for evaluation.

Scenario O is the base situation when we assume that there is no activity happens at our study areas. It means that all the trips contribute by our selected land-uses will be cut down totally. All the calculation for other scenarios will be calculated based on scenario O.

After that two more scenarios 5A, and scenario 5B are developed based on the scenario 5 with assumption that people will move along to live in newly-built residential areas, near the new locations

6.1. Scenario 0: No activity

This scenario is proposed to see the maximum possibility we can achieve in case there is no activity in our study areas. This task is easily completed by subtracting the contribution of these land uses and recalculate the congestion level and congestion mark (For detailed calculations, please refer to appendix D). The results are summarized in the table below:

| | Congestion Mark-Ocenario O-No Activity (nequencies) | | | | | | | | | | | | | |
|----------------|---|--------|-------------------|---------------------|---------------------|----------------------|-------------------|------------|--|--|--|--|--|--|
| | Mark | Weight | Morning Way In | Morning -Way Out | Afternoon-Way In | Afternoon-Way Out | Sum Scenario B | Total Mark | | | | | | |

| Severe G2 | 5 | 4 | | | | | | -40 | -32 | | | | | |
| Very severe G1 | 2 | 1 | | | | | | -36 | -18 | | | | | |
| Very severe G2 | 3 | | | | | | | -72 | 0 | | | | | |
| Craw | 1 | | | | | | | -30 | 0 | | | | | |
| Sum | | | | | | | | -244 | 352 | | | | | |

Table 6.2: Comparison between Current Situation and scenario O

From table 6.2, we can see that in Scenario O we can cut down almost of severe G1 cases, from 40 to 7 cases only, and increase quite a lot "No congestion" and "Migrate" cases, from 8 to 20 and from 10 to 26 respectively.

The figures below will give us a view of the ideal scenario, scenario O, in case of no activity. The scenario is compared with current situation by putting them together side by side.

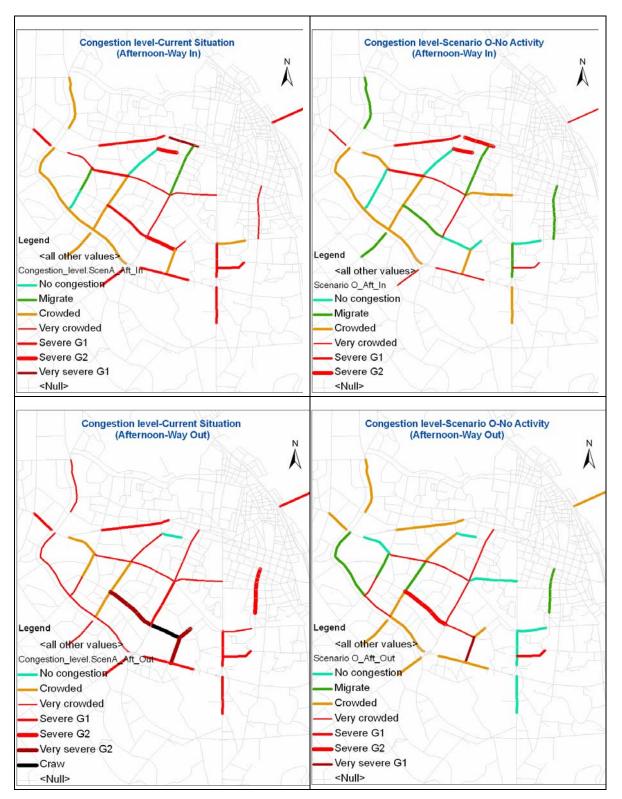

Figure 6.1: Comparison between Current Situation and Scenario O

| | Comparision of congestion level of some selected corridors | | | | | | | | | | | | | | |

| 12 | Thai Ha | No. 14-ThaiHa | Crowded | Severe G2 | Severe G1 | Very severe G2 | No congestion | Severe G2 | Migrate | Severe G2 | | | | | |

Table 6.3: Comparison of congestion level on some selected corridors

From figure 6.1, one can still observe some congestion symbol, particularly on some main corridors. However, from table 6.3, one can see that the congestion grade of these corridors is much better because the congestion grade of these corridors is much lower than before, for example Chua Boc street will move from "Craw" level to "Very crowded" on the way out in the afternoon and Thai Ha from Severe G1 to Migrate on the way-in in the afternoon.

This scenario, however, is not realistic, therefore in next paragraphs a scenario will be presented and discussed that more resemble current thinking in Hanoi.

6.2. Scenario 1: Road Expansion & No relocation

Many people think that the congestion situation can be relieved after some roads have been constructed or expanded and some new bridges are built. We will test this situation to see how much can we achieve by doing this.

6.2.1. Road to be expanded

According to plan of transport sector, 4 new bridges will be built: Thanh Tri Bridge, Vinh Tuy Bridge, Nhat Tan Bridge and Tu Lien Bridge. Thanh Tri Bridge has been put on operation on February 3rd, 2007. Besides that the ring road no. 1, no.2, no. 2.5 and ring road no.3 will be expanded. Most of them will be constructed before 2010 (M.O.T 2004).

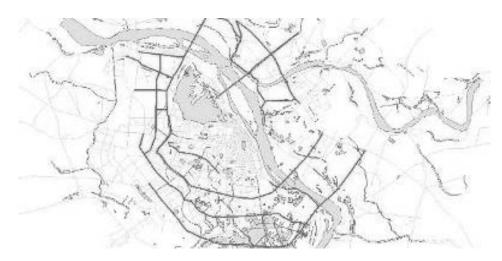

Figure 6.2: Roads to be expanded

One characteristic of Hanoi road network as mentioned before is that within the ring road no.2 it is very difficult to expand due to population density and the cost for land acquisition are very high. Therefore, most of the roads to be constructed or expanded are outside ring road no.2, except for ring road no. 1 only. Some parts of ring road no. 3 have already been completed for the SEAGAME 22.

| No. | Road name | Road width (m) | No. of lane/ direction | Year of construction (planned) | Note |
|-----|--|----------------------|---------------------------|--------------------------------|--------------------|
| 1 | Ring road No.1 (La Thanh and Buoi streets) | 50-60 | 3 | 2005-2007 | Under construction |
| 2 | Ring road No. 2 (Truong Chinh and Lang streets) | 53.5 | 3 | Before 2010 | Not start yet |
| 3 | Ring road no. 2.5 | 50-60 | 3 | Before 2010 | Not start yet |
| 4 | Ring road no. 3 | 68-74 | 4 | Before 2010 | Already started |

Table 6.4: Plan for expanded roads

6.2.2. Their new capacity in Non-peak hour

Based on this information, the whole road network is updated and road capacity of some corridors is re-calculated as shown in table 6.5 below. This new road capacity will be applied in calculation of congestion level in this scenario as well as in scenarios 4, 5, 5A, 5B.

| | Capacity of some main roads and corridors_After Expansion | | | | | | | | | | | | | | |
|-----|---|----------------|----------------------|--------|-----------|-------------------|--------------------------|----------------------------|---------------------------|----------------------|------|---------|------|------|-----------------------------|
| No. | Road name | Corridor code | Road width(m) | Oneway | Road type | Number of lane | Average length (m) | Average speed (km/h) | Average speed (m/s) | Lane width (m) | K1 | α | Σγn | Y | Road capacity (pcu/h) |

Capacity of some main roads and corridors_After Expansion

Table 6.5: New capacity of expanded corridors

6.2.3. Change in route used

Due to the road expansion, the characteristics of different corridors in our study areas will change. Newly-expanded roads will attract more traffic and traffic volume on some corridors can be cut down as shown in the figures bellow. The process of route recording in 5.5.1 is repeated.

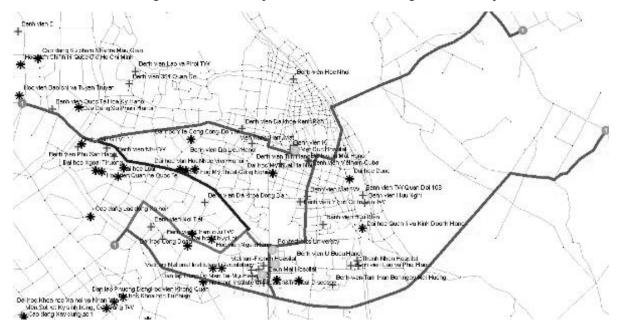

Figure 6.3: Change in route used

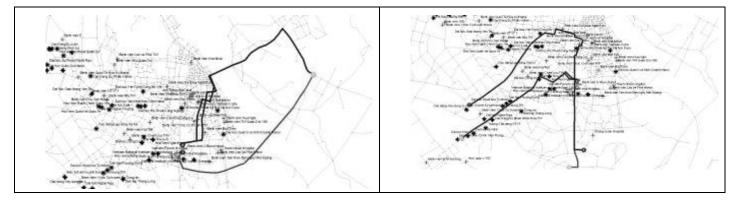

Figure 6.4: Change in route used for people from the East and the South

We can see quite clearly that people living in the South and the South West still use the same routes to our study areas; People living in the North West will use ring road no.1 instead of Thai Ha-Chua Boc-Pham Ngoc Thach route to study area no.1 but they keep the same route to study area no.2; People living in the East use the same route to Polytechnics University, but use different route to the remaining destinations; People living in the North will use Tu Lien or Nhat Tan bridges instead of Chuong Duong bridge. Routes are recorded separately for each organization and for both the way-in and the way-out.

In general, the traffic volume on corridors: Chua Boc, Pham Ngoc Thach, Cau Giay, Cau Chuong Duong, Ba Trieu and Pho Hue may have some cut down. The matter here is that most of our trip origins are from the South and South West. So we just know how much can we reduce after calculation in the next part.

6.2.4. Change in the congestion situation

New traffic volume on corridors during peak hours is re-calculated by adding the extra volume contributed by scenario 1 with traffic volume of scenario O in case no activity happens at our study. The calculation is done as follow:

New Traffic Volume = Traffic Volume of Scenario O + Contribution of scenario 1 (9)

(For detailed, please see appendix E & F)

And then congestion level and congestion mark are calculated. The result is summarized as follows:

| | Congestion Mark-Scenario 1-Road Expand-No Relocate (nequency) | | | | | | | | | | | | | |
|----------------|---|--------|-------------------|---------------------|---------------------|----------------------|-------------------|------------|--|--|--|--|--|--|

| Craw | -10 | 3 | | | | | | 0 | | | | | | |
| \$ | Sum | | | | | | | 126 | | | | | | |

Congestion Mark-Scenario 1-Road Expand-No Relocate (frequency)

Table 6.6: Summarize table of congestion level and congestion mark-Scenario 1

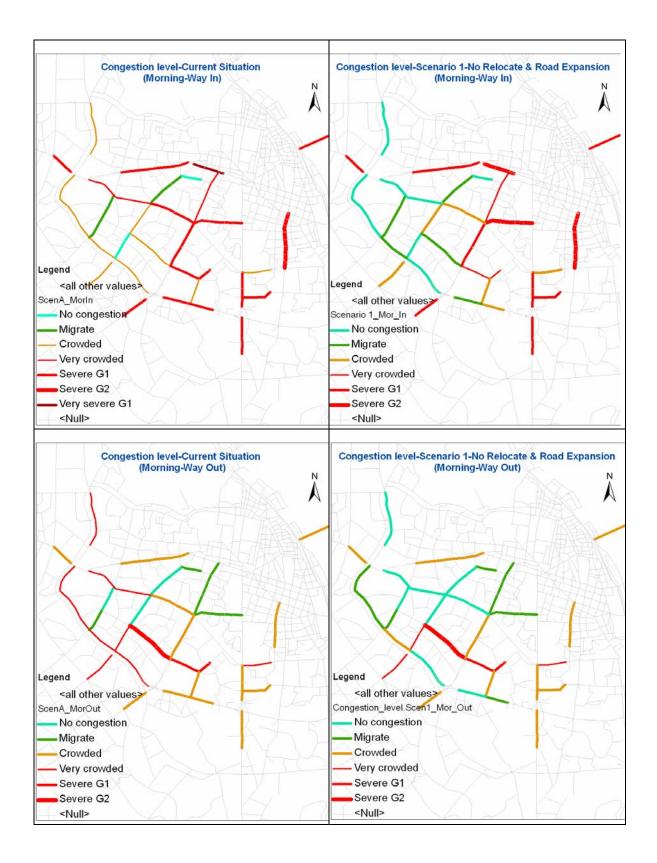

A comparison with Current Situation and Scenario O is also made.

Comparision of congestion level

| | | | | Sum case | | | | | | Cor | ngestion n | nark | | |
|----------------|----------------------|---------------|---------------|---------------|---------------|---------------|---------------|----------------------|-----|---------------|---------------|---------------|---------------|---------------|
| | Current Situation | Scenario O | Scenario 1 | Scenario 2 | Scenario 3 | Scenario 4 | Scenario 5 | Current Situation | | Scenario 1 | Scenario 2 | Scenario 3 | Scenario 4 | Scenario 5 |
| No congestion | 8 | 20 | 30 | | | | | 80 | | 300 | | | | |
| Migrate | 10 | 26 | 18 | | | | | 80 | 208 | 144 | | | | |
| Crowded | 38 | 49 | 31 | | | | | 76 | 98 | 62 | | | | |
| Very crowded | 31 | 31 | 14 | | | | | -62 | -62 | -28 | | | | |
| Severe G1 | 40 | 7 | 32 | | | | | -240 | -42 | -192 | | | | |
| Severe G2 | 5 | 4 | 8 | | | | | -40 | -32 | -64 | | | | |
| Very severe G1 | 2 | 1 | 4 | | | | | -36 | -18 | -72 | | | | |
| Very severe G2 | 3 | | 1 | | | | | -72 | 0 | -24 | | | | |
| Craw | 1 | | | | | | | -30 | 0 | 0 | | | | |
| Sum | | | | | | | | -244 | 352 | 126 | | | | |

Table 6.7: Comparison between Current Situation, Scenario O and Scenario 1

We can see that the situation has been improved a lot, but the number of cases at "Severe G1", "Severe G2" and "Very Severe G1" is still high. That is why the total congestion mark is only 126.

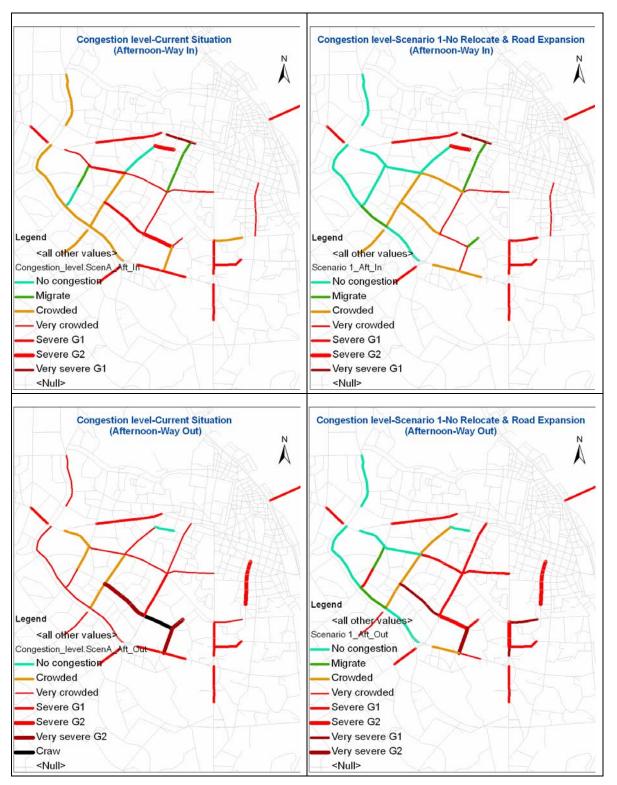

Figure 6.5: Comparison between Current Situation and scenario 1

In the morning peak hour, there is some improvement for ring road no.1 and ring road no. 2, and a small improvement for the other corridors. But in the afternoon, the congestion situation is almost the same. Therefore, we can conclude that road expansion alone can not relieve the congestion.

Therefore, in the next scenario, Scenario 2: "Relocate all organizations to the West & No road expansion" is studied to see now relocation can improve the situation.

6.3. Scenario 2: Relocate all to the West direction & No road expansion

This scenario is proposed since many organizations want to move out of the city centre. The current office is so narrow and it is quite difficult to expand the office because of some restrictions such as strict construction regulation and other regulations on construction tax in the urban core, etc. The second reason is that the existing land in the city centre has a high value. Therefore, by selling the existing land they can buy much bigger space in the outskirts. Land-use is moved to Western direction because the government has a policy to expand the city into this direction and in reality this area has less affect from Red river in the rainy season, cheap open land and good infrastructure which have been prepared in recent years. In near future, one highway Lang-Hoa Lac will be built with 100-140m road width. This area is also in connection between the existing the city centre and some new satellite cities on the West like Mieu Mon, Hoa Lac, Son Tay, Vinh Phuc, etc in the future. Some organizations have moved there and many others also want to move like Ministry of Science and Technology, Ministry of Agriculture, Ministry of Post and Telecommunications, National Assembly House, etc.

This scenario studies what will happen if all of them will move to the West direction. This scenario is also TRUE in case only 50% of government offices move to the West and another 50% of business enterprises also move to the West since the total number of people in business enterprises is almost the same with government staff as mentioned before.

In this scenario, it is assumed that people's residences in the wards stay the same. Furthermore, it is assumed that people remain travelling to these locations. In other words, relocation doesn't affect trip origins and destination choice (except for the physical location). These assumptions are realistic for Hanoi because of the specific land-uses functions and difficulty in moving houses.

6.3.1. New locations

For universities, the new location are known for the new base is in between Tay Mo and Dong Mo wards as mentioned in the proposal of Ministry of Education (please refer to 5.4.2).

For hospitals and government offices, it is assumed that the new location is the same or near the newly planned location of Ministry of Science and Technology and National Institute of Hematology and Blood Transfusion as mentioned before, in 5.4. It does not change very much on route uses if their new locations are around the specified location.

6.3.2. Change in traffic flow and route used

An interesting fact is that instead of using the way-in in the morning and the way-out in the afternoon the traffic flow will now move on the reverse directions: they use the way-out in the morning and the way-in in the afternoon. People also use different routes to go to new offices, especially people from the Southern and from the Western direction. This is depicted in the figure below.

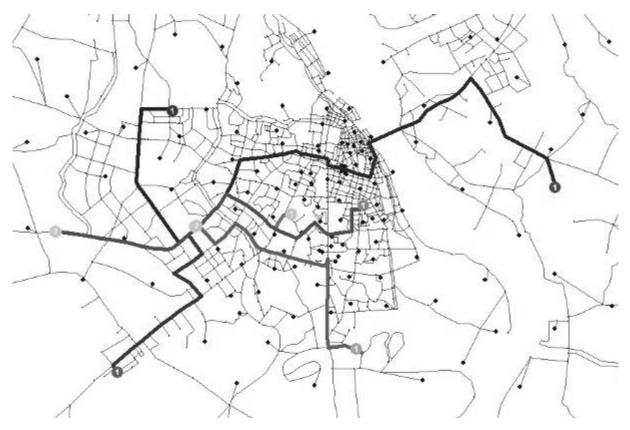

Figure 6.6: Change in routes used-Scenario 2-Relocate all to the West

It can be observed that people from the West or South West direction will not use the selected corridors. But people from the South and people from the city centre still use the selected corridors but in the reverse directions. People from the other side of the river still use Chuong Duong Bridge as an exclusive choice.

6.3.3. Congestion level & congestion mark

There is one aspect that needs to be taken into consideration. People take reverse directions with before to go and return from new locations.

The traffic volume on corridors is re-calculated as follow:

Traffic Volume (Morning-Way In) = Volume in Scenario O (10)

And the equation below is applied for the rest.

New Traffic volume =Volume in Scenario O + new contribution of scenario 2 (11)

And then congestion level and congestion mark are re-calculated and summarized in the table below. (For more details, please refer to Appendix G)

| | Mark | Weight | Morning Way In | Morning -Way Out | Afternoon-Way In | Afternoon-Way Out | Sum Scenario 2 | Total Mark | | | | | |
|----------------|------|--------|-------------------|---------------------|---------------------|----------------------|-------------------|------------|--|--|--|--|--|

Table 6.9: Comparison of congestion level and congestion mark between scenarios

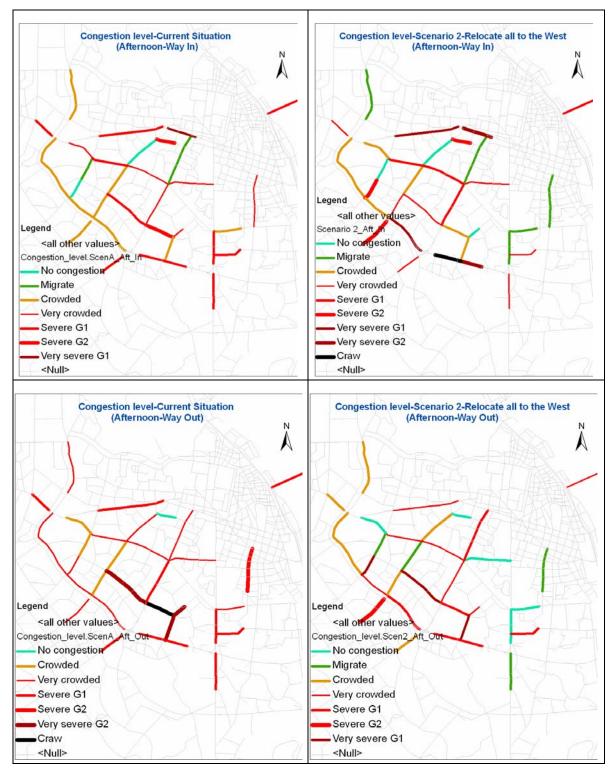

Figure 6.7: Congestion situation before and after relocating all to the West

It can be seen that the situation is worse than scenario 1, since it produces more congestion in the reverse directions, even the number of severe cases and very severe cases are more than in the current situation, especially the way-in in the afternoon.

Therefore, it can be concluded that traffic congestion can not be relieved by relocation alone. In the next scenario, scenario 3-"Relocate 50-50 & No road Expansion", a combination of relocation and road based measures will be investigated.

6.4. Scenario 3: Relocate 50-50 & No road expansion

This scenario is constructed because when we relocate 50% the selected land-uses to the new locations and 50% still stays at the current locations it is possible to make a balance between the way-in and the way-out traffic. The second reason is that it is more realistic than scenario 2-Relocate all. And finally, the third reason is that if we just relocate 50% to new locations, while 50% still remains at the existing locations. This means that the land-use will not be changed to other purposes like commercial, residential, etc.

6.4.1. New traffic volume on corridors

It is necessary need to re-calculate traffic volume on corridors with a consideration that in the morning 50% of them will use the way-in, 50% of them will use the way-out and in the reverse directions in the afternoon. Therefore, new traffic volume on corridors is calculated as follows:

New Vol. =Vol. of Scenario O + (Current contribution + Contribution of scenario2)/2 (12)

Then the congestion level and congestion mark are also recalculated (For details, please refer to appendix H).

6.4.2. **Congestion situation**

The result is summarized in the table below.

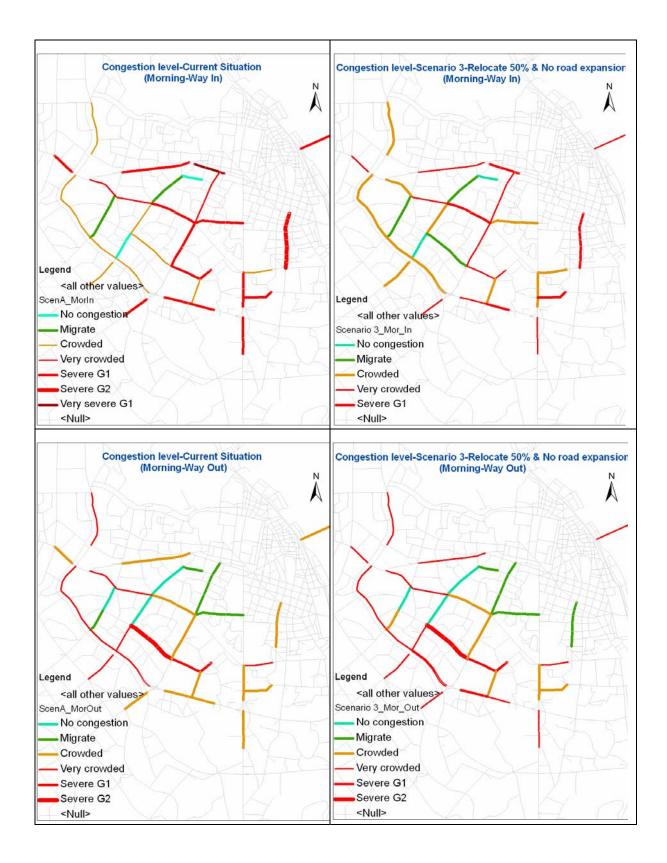

| Cong | cotion ma | | | | | | Inequenc | y) |

| Craw | 1 | | | 1 | 0 | | | -30 | 0 | 0 | -30 | 0 | | | | |
| Sum | | | | | | | | -244 | 352 | 126 | 12 | -56 | | | | |

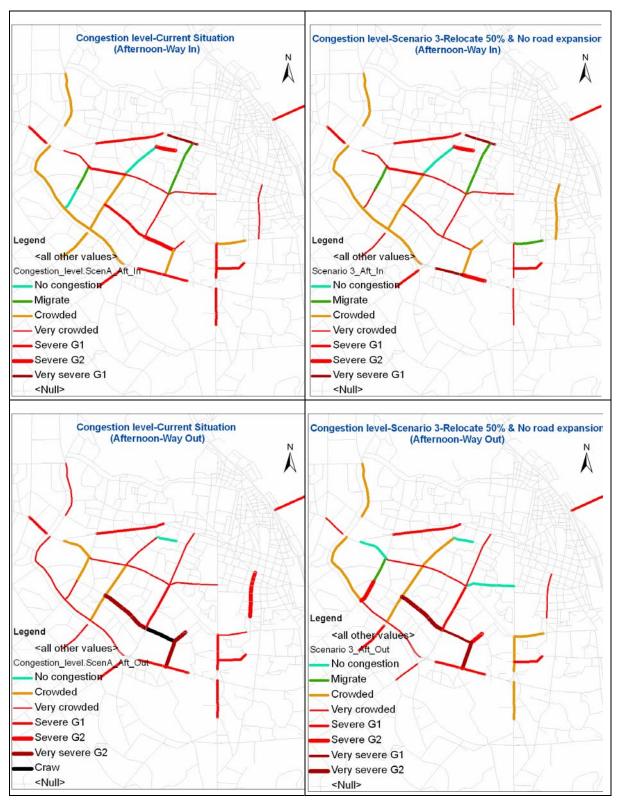

Figure 6.8: Comparison Current Situation and Scenario 3

It can be seen that this scenario can reduce the number of "Severe G1" cases from 40 to 22, but at the same time increase the "Very Crowded" cases from 31 to 45. This solution has considerable effect in terms of relieving traffic congestion as compared to the current situation. In the next scenario, scenario 4-Relocate all to the West combines with road expansion, all land-uses will be relocated while road capacity is also expanded.

6.5. Scenario 4: Relocate all & Road expansion

From scenarios 1 and 2, it can be seen that the situation is improved quite a lot. Therefore, in this scenario all strong points of these solutions are combined.

6.5.1. Change in route used

To apply this scenario all the corridors used to travel from one ward to the new locations have recalculated because newly-expanded roads are more attractive and people can run faster to the new locations on those roads. This is true for people living outside the ring road no.2, for people who live within the ring road no. 2 the situation does not change very much since they have no choice. This is shown in the figure below.

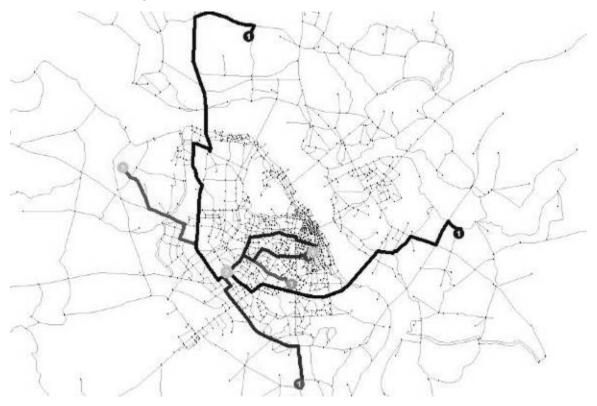

Figure 6.9: Change in route used-Scenario 4-Relocate all & Road Expand

6.5.2. New congestion level and congestion mark

New traffic volume running on corridors is re-calculated as follows:

New volume = Volume of Scenario O + New contribution of scenario 4 (13)

(For more details, please refer to Appendix I)

And then the congestion level and congestion mark are recalculated (using the expanded road capacity) and summarized in the table below.

| | Cong | estion M | ark-Scenaric | o 4-Relocate | All & Road E | xpansion (fre | equency) | |

| Sum | | | | | | | | -244 | 352 | 126 | 12 | -56 | 350 | |

Table 6.13: Comparison between scenarios (A,B,1,2,3,4)

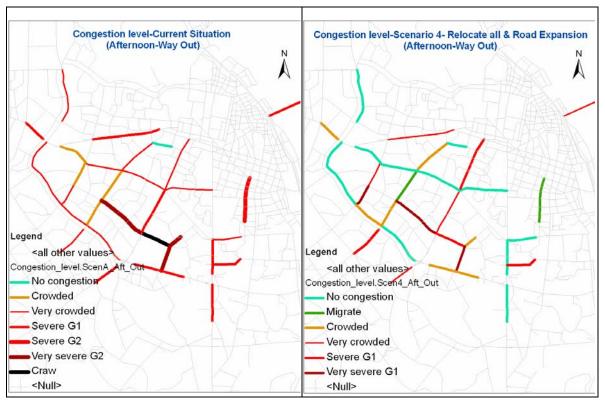

Figure 6.10: Comparison between Current Situation and Scenario 4

It can be seen that the situation has been improved very much. Compared with ideal Scenario O, this solution can achieve 99.43% (350/352) of ideal situation. Anyway, some corridors are still very busy such as Kim Ma, Nguyen Thai Hoc, Cat Linh on the way-in in the afternoon and Ton That Tung, Thai Ha on the way-out in the afternoon. Therefore, in scenario 5: Relocate 50% combine with road expansion is proposed to see if the situation can be improved.

6.6. Scenario 5: Relocate 50-50 & Road expansion

This scenario is constructed with an idea that after expanding road only 50% of the organizations will move to their new locations, 50% of them remains at the existing bases. They still keep the existing bases as head quarter (for government offices), or for higher education or treatment (for universities and hospitals). They do not convert land to other purposes like commercial, residential, etc.

6.6.1. Calculate new traffic volume

Since after expanding roads, 50% of the people will go to new bases and 50% still stays at the existing locations. Therefore, the traffic volume on corridors is re-calculated (with upgraded road capacity) for both the way-in and the way-out as follows:

New Volume = Volume of Scenario O + (Volume of scenario 1+Volume of scenario 4)/2 (14)

(For more details, please refer to appendix K)

6.6.2. Congestion situation

Again calculate congestion level and congestion mark are calculated. The result is summarized in the table below:

| | Conge | SUON NG | ark-Scenario | 5-Relocate t | | -xpansion (ii | equency) | |
|----------------|-------|---------|-------------------|---------------------|---------------------|----------------------|-------------------|------------|

Comparision of congestion level & Congestion Mark between Scenarios

Table 6.15: Comparison between all scenarios

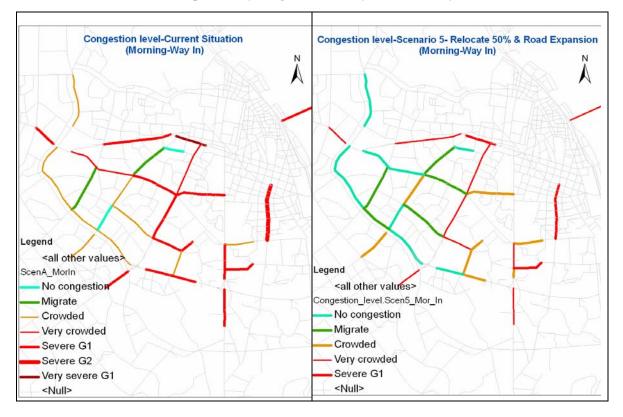

It can be seen that scenario 4 has the highest mark of all scenarios, just after the ideal situation in Scenario O, which assumes that there is no activity at all. By comparison scenario 5-Relocate 50% combined with road expansion can achieve about 67% (236/352) of the congestion mark for the ideal situation. It is a considerable achievement.

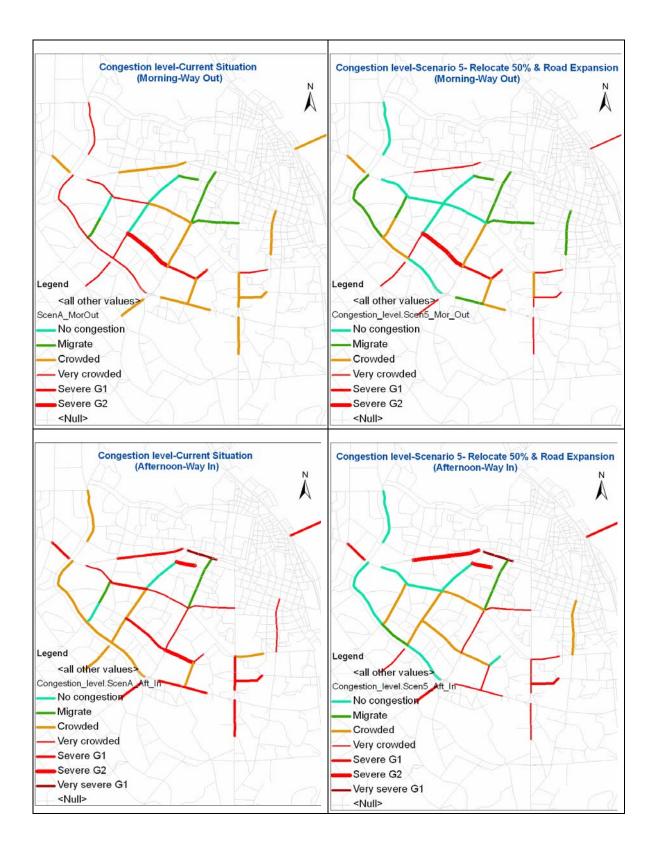

By relocating 50% of organizations combined with road expansion, the "Severe G1" cases can be reduced from 40 to 15 and increases the number of "No congestion" segments from 8 to 28, also increasing the number of "Migrate" segments from 10 to 17.

A comparison between scenarios is made for each travel direction as in the tables below

| | | | | | | | | | | | | | | | | | | 1 |
|-----------------------------------|---|--|------------------------------------|--|--|--|----------------------------------|-----------------------------|---|-----------------------------------|---|--|---|--|---|---------------------------------|-----------------------------|---------------------------------|

Table 6.16: Comparison of congestion level of all scenarios for each direction

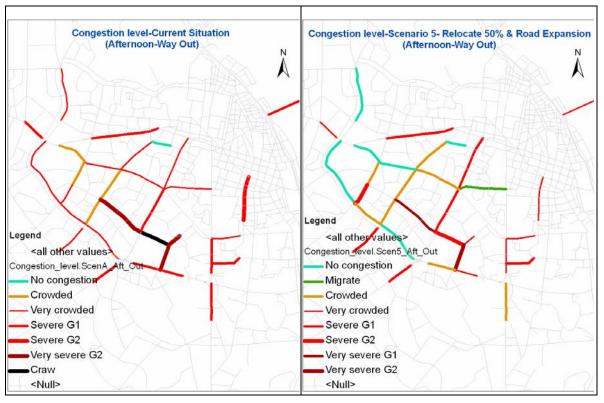

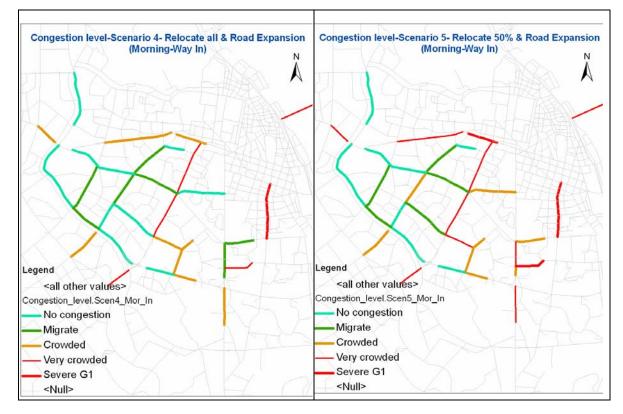

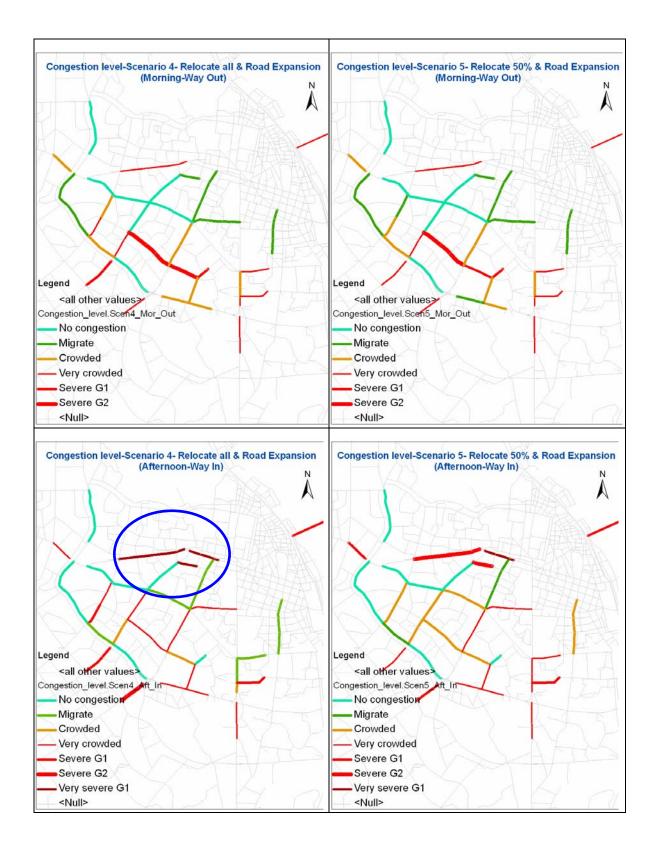

Figure 6.11: Comparison between Current Situation and Scenario 5

In general, the congestion has been relieve quite a lot except for Ton That Tung, Thai Ha streets in the afternoon-the way-out which is still under high pressure.

6.7. Comparision between Scenario 4 and Scenario 5

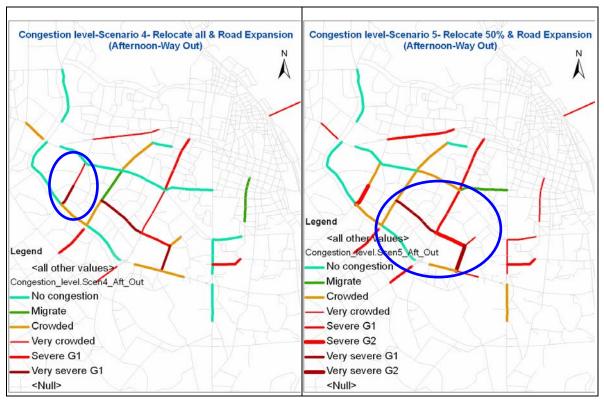

Figure 6.12: Comparison between scenario 4 and scenario 5

The most critical now is the way-out situation in the afternoon at Ton That Tung, Chua Boc, Thai Ha streets. By comparing scenarios 4 and scenario 5, it can be recognized that in the afternoon for both the way-in and the way-out, the scenario 5 is more in balance than scenario 4, because in scenario 4 even it produces more "No congestion" and "Migrate" cases, but the congestion level on some corridors like Nguyen Chi Thanh street is more severe than in scenario 5. Therefore, even scenario 4 has a higher congestion mark than scenario 5, but in general scenario 5 is more in balance.

6.8. Change in trip origin

This scenario is constructed with the assumption that some percent of people will also move along to new bases. This assumption is quite realistic since in the Western and the Southern direction of the existing the city centre, especially around the new proposed bases, many newly-built residential areas have been constructed with good infrastructure as depicted in the figure below.

Figure 6.13: Newly-built residential areas

In recent years, from 1999 to 2005, population in these areas (Thanh Xuan, Cau Giay, Tu Liem, and Hoang Mai district) have increased with about 6% on average as indicated in the table 3.1. In the future, the number of people moving out is expected to be more since the construction has been accelerated, the house quality is better, and the price is getting cheaper. That is the policy of government to attract people moving out from the city centre.

6.8.1. Scenario 5A

If we assume that 18.0 % (6% * 3 times) of people in the city centre (Hoan Kiem, Ba Dinh, Dong Da, and Hai Ba Trung districts) will move out to new residential areas, especially Dinh Cong, Hoang Liet, Thanh Xuan, Trung Hoa, Me Tri, My Dinh wards.

This calculation is applied for Scenario 5, named Scenario 5A. We will cut down 18.0% of all trips from the city centre and distribute equally the total number of cut-down trips to 6 wards mentioned above. This calculation is applied for each organization separately for morning peak and afternoon peak hour (The reason is that people use different routes to the organizations); the traffic volumes on the corridors for scenarios 1, 4 and 5 have been re-calculated. There is one assumption that the person who has moved to new residential areas will work/study at the new locations and not use the selected corridors for both morning and afternoon. Therefore, the calculation is basically done with 18% cut-down of all the trips from the city centre.

| Sum | | | | | | | | | -244 | 352 | 126 | 12 | -56 | 350 | 236 | 250 |

The result is summarized in the table below.

Comparision of congestion level & Congestion Mark between Scenarios

Table 6.17: Summary congestion level and congestion mark of scenario 4A, 5A

We can see that the situation has been improved, but not very much. Therefore, in the next scenario 5B, it is assumed that 50% of people will move along to the new locations.

6.8.2. Scenario 5B

This scenario is constructed with an assumption that government's policy is successful, which attracts 50% of staffs moving out from the city centre to live in new residential areas. Assume that those persons will work at new bases. The calculation is similar to scenario 5A with the cut-sown of 50% all the trips from the city centre.

The result is summarized as follows (For more details, please refer to appendix L).

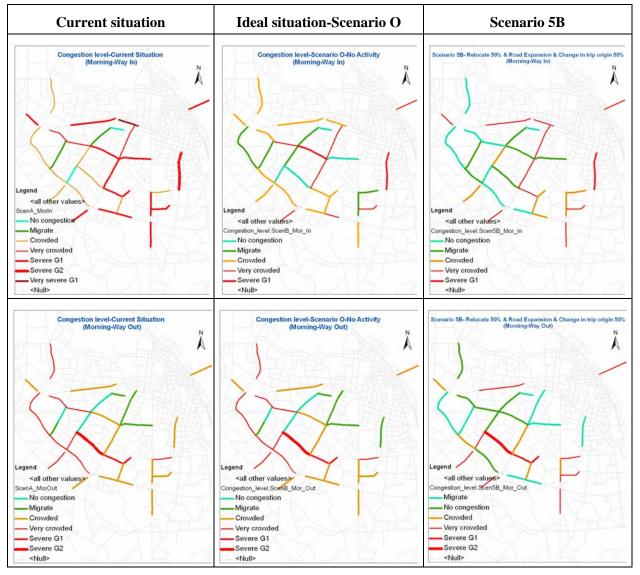

| Comparision of congestion level & Congestion Mark between Scenarios | • |

Table 6.18: Comparison congestion level and congestion mark of Scenario 5B with others

It can be seen that the situation is improved a lot. It comes near to the ideal situation, scenario O, which assumed that no activity happens at the study areas.

This will be compared with the current situation, situation in Scenario 5B and ideal situation of Scenario O.

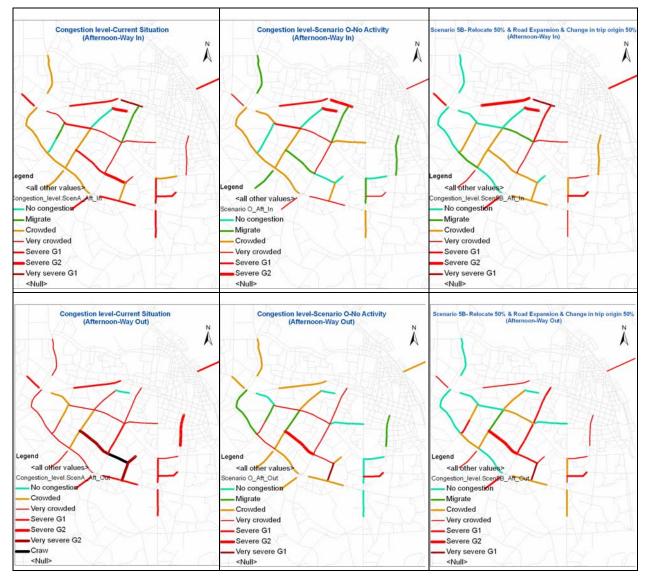

Figure 6.14: Comparison between Current situation, Scenario O and Scenario 5B

It can be seen that the congestion have been relieved in almost corridors for both morning peak and afternoon peak, except Thai Ha, Kim Ma and Nguyen Thai Hoc streets. A possible reason is that Ba Dinh district where 93,331 government staffs working attracts huge people in the morning and also release huge people in the afternoon.

6.9. Conclusions

In this chapter, six scenarios have been constructed for evaluation of traffic congestion. The result of scenarios gives us a clear view that infrastructure alone or relocation alone can not solve traffic congestion, only by a combination between infrastructure and relocation we can have achievement in relief traffic congestion. Even scenario 4 has higher congestion mark than scenario 5 but scenario 5, relocate 50% combine with road expand, is more balance between the way-in and the way-out. Further more, relocate 50% is more realistic in Hanoi situation. Finally, scenario 5B is a modification of scenario 5 with an assumption that 50% of people will move out of the city centre to live in the newly-built residential areas and work at new locations shows that it comes near to the ideal situation in scenario 0 with 90% (318/352). It gives us a suggestion that together with

combination between road expansion and relocation government should have good policy on housing to attract more people moving out from the city centre to live in newly-built residential areas.

In conclusion, by integration between land-use and transport and in this case is the combination between road expansion and relocation, the traffic congestion can be relived considerably.

7. Conclusions and Recommendations

7.1. Conclusions

In this research, the contribution of some selected major land uses to the traffic congestion on some corridors is evaluated. Different scenarios of relocating (part) of these land-uses have been formulated and tested in order to see to what extend traffic congestion is relieved and accessibility have been improved for the people of Hanoi, Vietnam.

Based on existing government plans, two study areas have been proposed for evaluation, i.e. study area no.1, which is Bach Mai area, where three big universities with almost 70,000 students and a group of hospitals are located, and study area no. 2, which is in the urban core (Hoan Kiem district), where three big hospitals and 161 government offices at the national level with around 16,218 staffs are located. In total, five hospitals, three universities and two government offices were therefore targeted for cordon counts and office-based interviews to retrieve information on total numbers of trips arriving at these locations in and outside peak hours, the trip origins, travel time, travel length, transport mode and routes used.

All main corridors and congested roads leading to these destinations were selected and then divided into 36 road segments for evaluation of the levels of traffic congestion that can be attributed to these land-uses in both the morning peak and afternoon peak as well as both the way-in and the way-out.

The research reveals that these land-uses contribute considerably to traffic congestion of some corridors nearby. For example, the study area no.1 has considerable contribution to Chua Boc, Pham Ngoc Thach, and Thai Ha streets with shares of about 23%, 27% and 23% respectively just on the way-in in the morning peak hour while in the afternoon peak hour they contribute to both the way-in and the way-out as for about 54.7%, 81.3% and 43.9% respectively on the way-in and 43.7%, 56.5% and 27.6% respectively on the way-out since universities release students from afternoon-classes around 17:15 PM and attract students to night-classes from 17:30 to 18:00PM. About 97.2% of students commune on these corridors during the afternoon peak hour. Study area no.2 contributes considerably to the other corridors such as Kham Thien, Nguyen Thai Hoc and Kim Ma with a contribution of about 68.7%, 42.5% and 26.2% respectively on the way-in in the morning and 72.8%, 0% and 37.8% on the way-out in the afternoon. About 95% of government staff uses motorcycle and 95.5% of them commune on these corridors during peak hours.

The possibility for relieving the current congestion situation by expanding and building some roads and bridges alone, which is planned by Ministry of Transport, is investigated in the first scenario. Scenario no.1 shows that the situation can be improved by expanding road capacity, but the number of severe congested and very severe congested cases is still very high. Therefore, this strategy is fails in dealing with congestion appropriately.

A full relocation, without infrastructure measures, is studied in the next scenarios. Scenario 2 relocates all land-uses to the west, while in the following scenario 3 only 50% is relocated to the west. Both scenarios show that the situation even worse than scenario 1 because instead of

relieving congestion it produces more congestion on the roads in the reverse directions, while the number of severe and very severe cases is even more than in the current situation. Therefore, it can be concluded that relocation alone also fails in dealing with congestion.

In the next scenario, a combination between road expansion and relocation is studied. It can be seen from this scenario 4 where all the land-uses are relocated to the west in combination with road expansion that the situation is improved very much and it already comes near with the "ideal" base-line situation in scenario O. The base-line scenario assumes that there is no activity at all in our study areas anymore and that people simply abort making these trips. The number of segments with traffic segments rated "No congestion" and "Migrate" have been increased from 8 to 36, and from 10 to 24 respectively, the number of "Severe G1" is cut down from 40 to 11 cases, except for "very severe G1" which have increased in number from 2 to 6. Anyway, this scenario is not too realistic as it is very difficult to move all these organizations out of the city centre. Besides that the situation might be worse if the purpose of land-use changes to commercial or residential one. For that reason, in scenario 5 it is proposed that only 50% of organizations will move to new locations. The result shows us that the situation is improved very much as compared to scenario 1, which is expansion of road alone, and scenario 3, which is relocation alone. This scenario achieves 67% of the "lowest possible" congestion mark from the ideal situation of scenario 0. In short, it can be concluded that by combining road expansion and partly relocation, a considerable congestion relief can be achieved.

In addition, scenarios 5A and 5B have been proposed that assume 18% and 50% of people respectively will move to the newly-built residential areas for living, so a realistic change in trip origin is also assumed. Scenario 5A is not very much different from scenario 5. The result of scenario 5B shows that it comes very near to the ideal situation from scenario 0 with 90% of the "lowest possible" score. This shows that both road expansion and relocation plus an active policy of providing new housing by the government of Hanoi is necessary to attract more people for moving out from the city centre to live in newly-built residential areas.

All these analyses have been done by applying advanced spatial and network capabilities of GIS. The travel data has been gathered by performing a large-scale workplace survey and cordon traffic counts.

In conclusion, a further integration of land-use and transport can be achieved congestion relief if it is done in a combination between road expansion and relocation.

7.2. Limitations of this research

Due to limit in time, for this research only one indicator, i.e. the number of vehicles on corridors is applied for the evaluation. Other indicators like total travel length, total travel time, number of people shifting from motorcycle to green modes (walking, cycling, and bus) could have been used also for the evaluation because these will also benefit from relocating and road expansion policies.

In addition, current calculations have been based on some assumptions such as:

- People go from or return to their commune centre (homes). It means that the commune centre is used as the trip origin/trip destination.
- People use shortest route measured in travel time.

- Travel is considered as single-trip end. It means that people go directly to our study areas from their home and return directly as well.
- Assume all government offices in the urban core have the same characteristics (trip origin, mode share, travel time) with the surveyed ones.

The corridors used were recorded by hand. Since this is a time consuming task counts have only been performed in one representative peak per location. This may have caused some errors.

7.3. Recommendations

7.3.1. Recommendations for transport and land-use policy in Hanoi

In order to achieve sustainable transport in Hanoi, some suggestions have been raised based on the findings and conclusions in this research as follows:

- Some major land-uses like government offices, universities, hospitals, schools, etc should be considered for redistribution and relocation, especially offices in the urban core and Ba Dinh district, in order to lower the density people numbers in these areas and encourage people to use green modes before deciding high-cost investment for metro and expanding roads. Traffic congestion can be relieved as a consequence.
- Bachelor students (account for 50% of total students as mentioned in 5.4.2) should be stimulated to move out to new locations. The existing bases should be kept for higher education and other courses like second-degree course, and in-service courses.
- In combination with relocation policy, government should have good policy to attract more people moving out from the city centre to live in newly-built residential areas such as supply low cost apartments, house renting policy, etc.
- Some restriction policy should be applied for the urban core (Hoan Kiem district) to reduce people and activities and return this area attractive for tourism. For example, offices which have more than 50 staff should be moved out, especially government offices, foreign offices, and business enterprises; only head-quarter offices can be remained in the urban core; new high-rise buildings is not allowed to construct in the urban core, etc.
- Facilities for cycling and walking like cycling path, cycling and walking signals, etc should be installed to further encourage people to use these green modes instead of using private vehicles (The existing policy does not encourage people using these mode as mentioned in 3.5).
- Some basic social facilities like hospitals and universities should be redistributed to achieve equity and better accessibility for people in the whole city.

7.3.2. Recommendations for further studies and improvement

Due to the time limit, for this research only one indicator (number of vehicles on a corridor) is applied for evaluation. It is recommended to apply the other indicators like total travel length, total travel time, number of people shifting from motorcycle to green modes (walking, cycling, and bus) for evaluation the benefit of relocating some major land-uses.

It is recommended to apply GIS application for facility improvement to encourage people using green modes using GIS application like designing cycling paths, private bus routes, etc.

It is recommended to study the criteria to suggest which group of offices and enterprises should be the best to move from the urban core and Ba Dinh district.

It is recommended to study how basic social facilities like hospitals, universities and schools should be redistributed to achieve social equity and better accessibility for people in the whole city.

Appendixes

Appendix A:

Giao thông Hà Nội: xây dựng mới, hay cơi nới cũ? (http://hinet.net.vn/news)

Để đạt chỉ tiêu đất dành cho giao thông đạt 20-25% đất đô thị tại nội thành Hà Nội, thành phố cần 15 triệu m2 với số tiền GPMB lên đến 210.000 tỷ đồng (khoảng 14 tỷ USD).

Bài toán khó: Giải thế nào?

9 quận nội thành Hà Nội có diện tích khoảng 110 km2. Tuy nhiên diện tích đường bộ của Hà Nội chỉ đạt khoảng 6km2 (gần 400 km đường), tương đương 6% diện tích đô thị.

Không chỉ diện tích đường thấp mà đường còn phân bố không đều. Quận Hoàn Kiếm có tỷ lệ đường giao thông đạt 12% so với diện tích đô thị, trong khi các quận còn lại tỷ lệ chỉ đạt 5%.

Tại các nước phát triển, quỹ đất dành cho giao thông đạt 20- 25% đất đô thị (đó là chưa kể diện tích ngầm và diện tích khoảng không xây dựng các công trình giao thông).

Để có thể giải quyết căn bản tình trạng ùn tắc giao thông tại Hà Nội, theo các chuyên gia, Hà Nội phải nâng quỹ đất dành cho giao thông lên 20% đất đô thị (tương ứng 20km2). Như vậy Hà Nội cần thêm 15km2 đất (14 triệu m2).

"... Cho đến nay Thủ đô Hà nội chưa có được một quy hoạch chuyên ngành, đồng bộ, toàn diện về phát triển giao thông vận tại được tôn trọng và đầu tư có hệ thống theo một chương thể đầu trự có hệ thống theo một

chương trình đầu từ trọng điểm quốc gia tưởng xứng với vai trò, vị trí của Thủ đô"

Trích Văn bản góp ý cho "Quy hoạch phát triển GTVT Thủ đô Hà Nội đến năm 2020" của UBND TP Hà Nội gửi Bộ GT-VT. Nếu lấy dự án đường Kim Liên-Ô Chợ Dừa làm chuẩn thì mỗi m2 đất có giá đền bù GPMB khoảng 14 triệu đồng.

Để nâng diện tích đất giao thông lên 20%, Hà Nội cần đầu tư thêm 210.000 tỷ đồng (14 tỷ đô la) cho việc GPMB. Nếu tính cả tiền xây lắp đường (khoảng 20% tổng mức đầu tư) thì mức đầu tư lên đến 17 tỷ đô la, (khoảng 250.000 tỷ đồng).

Và nếu xây dựng đường tàu điện ngầm và đường sắt chi phí này còn cao hơn nhiều.

Trước số tiền khổng lồ trên có hai luồng quan điểm. Một là: Hà Nội nên dành tiền đầu tư hạ tầng giao thông và phát triển khu đô thị mới với các loại hình dịch vụ, hạ tầng xã hội hoàn hảo, giá bán nhà rẻ. Khu vực từ vành đai 2 trở vào nên giữ nguyên hiện trạng, chỉ sửa chữa nhỏ.

Quan điểm này có ưu điểm là chi phí đầu tư thấp, sẽ giãn mật độ dân cư nội thành Hà Nội, theo đó giảm sức ép giao thông và kéo tụt giá nhà đất tại nội thành, tạo điều kiện để sau này mở mang, chỉnh trang đô thị. Tuy nhiên, làm được việc này cần phải có thời gian dài và bức xúc giao thông tại nội thành sẽ rất căng thẳng.

Quan điểm 2, vừa đầu tư xây dựng hạ tầng giao thông trong nội thành, vừa đẩy nhanh xây dựng mới các khu đô thị hấp dẫn người dân nội thành đến ở. Ưu điểm của phương án này là vừa giãn dân (lượng dân phải di dời do GPMB để xây dựng các công trình giao thông), đồng thời "xoa dịu" tình trạng ùn tắc giao thông trong nội thành.

Kèm theo đó, chính sách hạn chế phát triển khu vực nội thành phải được thực hiện nghiêm ngặt. Vậy nhưng, nếu cứ chú trọng xây dựng hạ tầng giao thông tại nội thành sẽ dẫn đến người dân không mặn mà đến các khu đô thị mới. Giá đất vẫn cao và cuộc "cách mạng" sẽ không đem lại kết quả cao. Thêm nữa, chi phí đầu tư của phương án này sẽ rất cao. Có điểm chung, cả hai quan điểm đều thống nhất "giãn khỏi trung tâm"!

Giãn cơ quan Nhà nước ra khỏi trung tâm

Với 15 tỷ đô la, các chuyên gia kinh tế cho rằng Hà Nội có thể hoàn toàn xây dựng được một trung tâm chính trị, kinh tế, y tế, giáo dục... mới nằm ngoài đường vành đai 3. Tuy nhiên, vấn để đặt ra là ai sẽ là người chịu di dời khỏi trung tâm Hà Nội? Giãn dân! Tất nhiên rồi, nhưng TP Hà Nội chưa hấp dẫn được người dân ra ngoại ô sinh sống.

Lý do là: hạ tầng xã hội yếu kém (chợ, bệnh viện, trường học, ngân hàng, khu vui chơi, giải trí...) chưa có. Thứ hai, giá nhà, đất tại các đô thị mới quá cao vượt sức mua của đại đa số người dân. Điều quan trọng là hầu hết trụ sở làm việc của các cơ quan, đơn vị vẫn nằm trong nội thành. Vì lý do đó, nhu cầu và quãng đường đi lại của người dân tại các khu đô thị mới tăng lên. ùn tắc giao thông không giảm. Người dân "cố thủ" tại nội thành.

Vì vậy, để có thể "giãn cư", Hà Nội cần phải có chính sách giãn các cơ quan ra ngoại ô. Năm 2001, quy hoạch chi tiết Làng đại học tại Đại Mỗ và Tây Mỗ (huyện Từ Liêm) được phê duyệt. Nếu như các trường Bách khoa, Kinh tế Quốc dân, Xây dựng được di chuyển, chắc chẳn sức ép về giao thông đô thị tại khu vực đường Giải Phóng, Bạch Mai sẽ được cải thiện đáng kể.

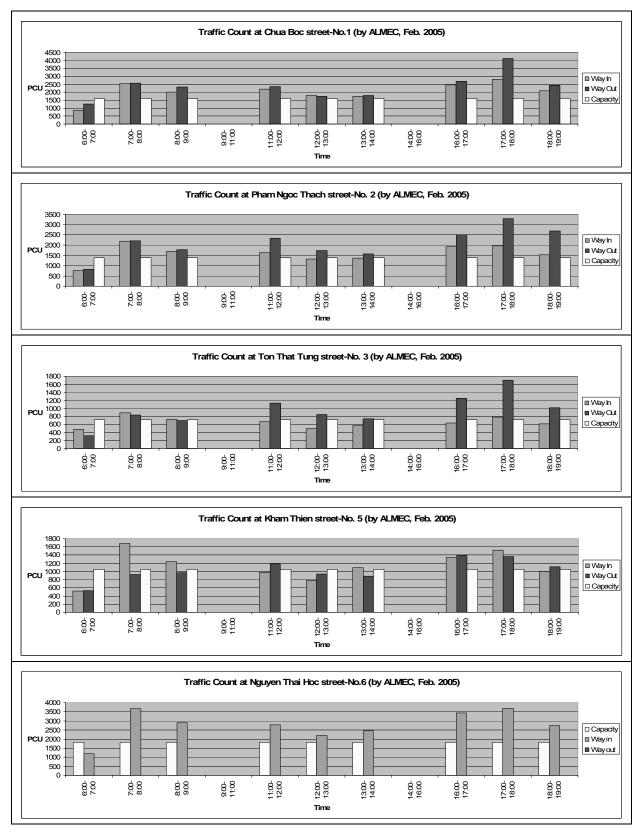

Rất tiếc dự án này đến nay chưa được triển khai. Bên cạnh các trường học, một số bệnh viện lớn cũng cần được giãn ra ngoài đường vành đai 3 thuận tiên cho việc ra vào viện của bệnh nhân từ các tỉnh đến như bệnh viện Bạch Mai, Việt Đức, Viện K, Viện C... Làm được việc này, một mặt chúng ta có điều kiện đầu tư một cách bài bản cho các bệnh viện, mặt khác làm giảm ùn tắc cho khu vực nội thành.

Đối với cơ quan hành chính? Năm 2004, Trung tâm Hội nghị quốc gia được xây dựng tại Mễ Trì. Dư luận kỳ vọng đây sẽ là dấu hiệu của một cuộc di chuyển các cơ quan hành chính ra khỏi trung tâm Hà Nội. Nhưng không, trụ sở một số Bộ tiếp tục được xây dựng hoành tráng ngay trung tâm phố cũ.

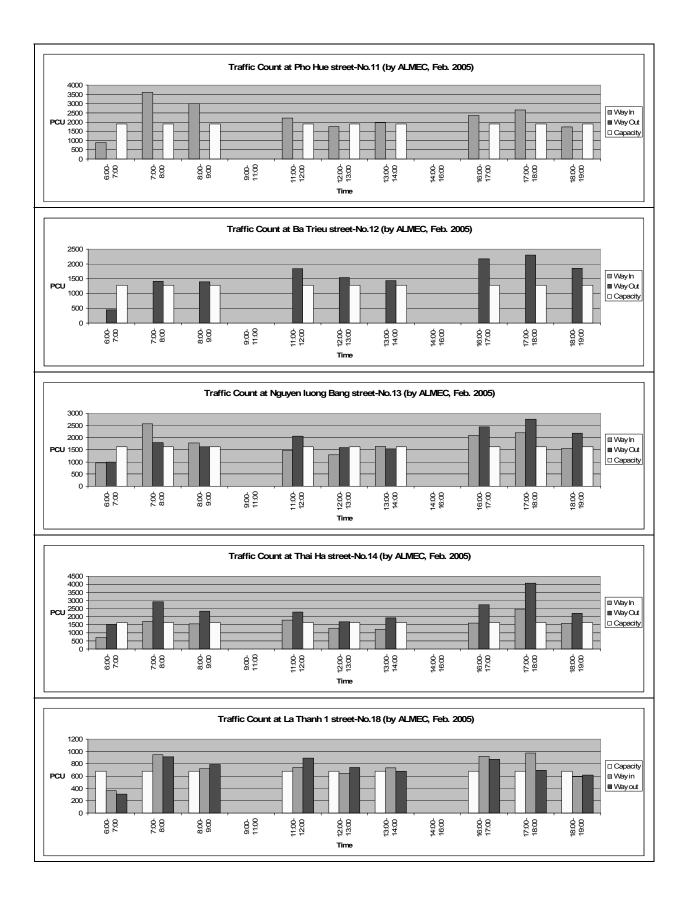

Trong bối cảnh ùn tắc giao thông nghiêm trọng, đầu tư xây dựng hạ tầng vô cùng khó khăn, để hóa giải bài toán giao thông, việc giãn dân ra khỏi nội thành là hết sức cần thiết. Tuy nhiên, để làm được việc này, Hà Nội cần phải có những chính sách cụ thể.

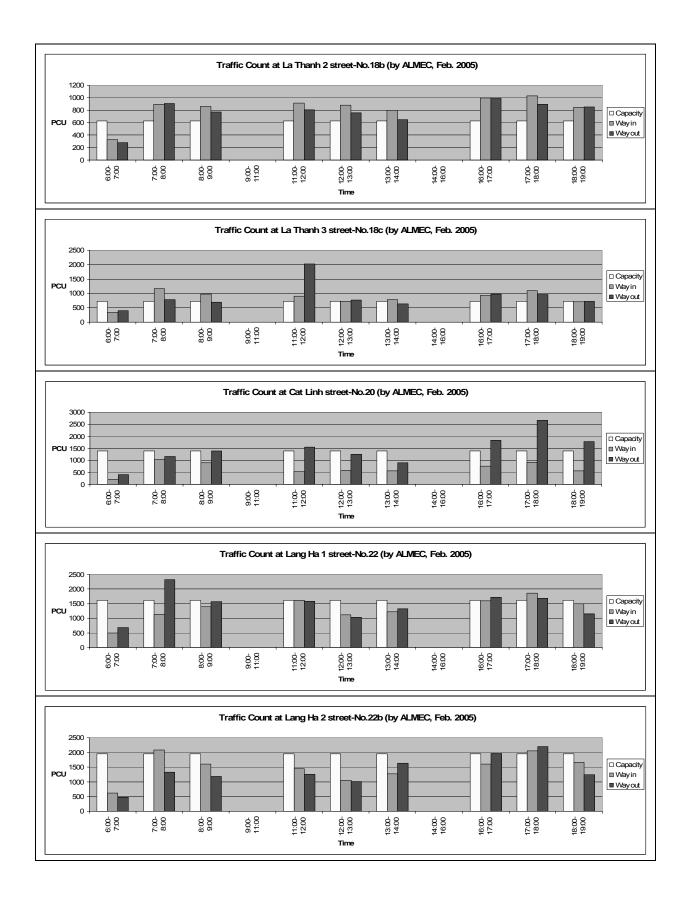

Ví như: chính sách bán nhà trả góp, hạ giá bán nhà chung cư, xây dựng hạ tầng kỹ thuật, hạ tầng xã hội cho đô thị mới tốt...Điều quan trọng, để khuyến khích người dân di dời khỏi trung tâm thành phố, thì bản thân các cơ quan hành chính của Trung ương và Hà Nội, các bệnh viện, trường học phải làm gương trước.
